ÖZET

Doktora Tezi

PARAFİN AKTİVATÖRLERİN İSİL HİSTEREZİS ÖZELLİKLERİİN İYİLEŞTİRİLMESİ İÇİN PARAFİN-NANOLİF NANOKOMPOZİT GELİŞTİRİLMESİ

Otomotivden, elektronik ve dayanıklı ev aletlerine kadar çok geniş alanda kullanıma sahip olan parafin aktivatörlerin en büyük sorunu parafin malzemesinin ısı iletkenliğinin düşük olması ve dolayısıyla ısil histerezis değerlerinin kötü olmasıdır. Bu çalışmanın amacı nanoliflerin takviyesinin parafin aktivatörlerin ısil histerezis özelliklerine etkisinin incelenmesidir. Öncelikle nanolif yüzeyi ve farklı karbon atom sayısına sahip sıvı parafinin etkileşimi elektroçekim yöntemiyle üretilmiş nanolif ile deneysel olarak değerlendirilmiştir. Tek iğneli uniaksiyel elektroçekim ile tek adımda hızlı ve kolay bir parafin/poliakrilonitril hibrid nanolif üretimi üzerine çalışmalar yapılmıştır. Üretilen hibrid parafin/poliakrilonitril yapısı parafin aktivatörün histerezis değerinin iyileştirilmesi için kullanılmıştır. Dört farklı erime noktasına sahip parafin çeşidi ile ağırlıkça %2.5, 5, 7.5 ve 10 oranlarında parafin/poliakrilonitril karışımı kullanılarak parafin aktivatör üretilmiş ve ısil histerezis değerinde %15.3 oranına kadar iyileşme sağlanmıştır. ısil histerezisde nanolif takviyesi ile elde edilen iyileşme, metal oksit nanoparçacık takviyesi ile kıyaslanmıştır. CuO, Fe₃O₄, ZnO, Al₂O₃ nanoparçacıkları ve poliakrilonitril nanolif takviyesi üretilen parafin aktivatör numuneleri, sırasıyla %24.6, 26.2, 20.0, 29.2 ve 30.8 oranlarında ısil histerezis iyileştirmesi gözlenmiştir. Dispersiyon ısil stabilitesinin, parafin aktivatörün histerezis performansına etkisini ölçmek için bu numuneler yüksek ısida yaşılandırma testine tabi tutulmuştur. Nanolif kullanımında histerezis değerinde en yüksek iyileşme görüldürken, yüksek sıcaklıkta yaşılandırma tetsi sonunda yine nanolif katkılı numune en düşük performans kaybına uğramıştır.

Anahtar Kelimeler: Nanolif, parafin aktivatör, histerezis, elektroçekim, poliakrilonitril

2022, xi + 133 pages.

ABSTRACT

PhD Thesis

DEVELOPMENT OF PARAFFIN-NANOFIBER NANOCOMPOSITE FOR THERMAL HYSTERESIS ENHANCEMENT OF PARAFFIN ACTUATORS

Supervisor: Prof. Dr. Yakup AYKUT

The most important problem of paraffin actuators, which are used in a wide range of technical areas from automotive engine cooling systems to electronics and household appliances, is the low thermal conductivity of the paraffin material and its poor thermal hysteresis. This study determines the effect of nanofiber addition on the thermal hysteresis behavior of paraffin actuators. Interactions of electrospun nanofibers mat with the liquid paraffins with different amount of carbon were also investigated. Preparation of paraffin/polyacrylonitrile hybrid nanofibers via single needle (uniaxial) electrospinning system was studied. As-spun paraffin/polyacrylonitrile nanofibers were used for thermal hysteresis enhancement. Paraffin actuators are prepared with paraffins of four different melting points consisting paraffin/polyacrylonitrile nanofiber with the wt.% of 2.5, 5, 7.5 and 10. The hysteresis value was enhanced up to 15.3%. CuO, Fe₃O₄, ZnO, Al₂O₃ metal oxide nanoparticles addition and polyacrylonitrile nanofiber addition are used for thermal hysteresis enhancement comparison and an improvement as 24.6, 26.2, 20.0, 29.2 and 30.8 % sequentially for the samples compared with pure paraffin. Dispersion thermal stability effect on hysteresis performance of those paraffin actuators are also compared and nanofiber added paraffin actuator showed at least hysteresis performance loss at high temperature storage test.

Key words: Nanofiber, Paraffin Actuator, Thermal Hysteresis, Electrospinning, Polyacrylonitrile

2022, xi + 133 pages.

PREFACE AND/OR ACKNOWLEDGEMENT

My passion for developing a paraffin actuator with enhanced thermal behavior especially for vehicle engine cooling systems is relying on the demand of innovation for the since long decades constant remained paraffin compound which is still suffering for thermally deaf and untouched micro-scaled structure. An innovative and affordable nanostructured solution will not only improve the engine performance of vehicles, but also protect the environment in terms of exhaust emission releases.

This thesis would not have been possible without the excellent guidance and support of my supervisor Prof. Dr. Yakup Aykut. I am very thankful to him for keeping me on track towards this demanding journey. I would also like to acknowledge the support of my co-supervisor Prof. Dr. Recep Eren during the recovery of my scientific study to research articles. It has been a pleasure working with them on this research and I look forward to future collaborations together.

I would like to express my thanks and appreciation to all my colleagues at Research and Development Center of Kirpart AS, and especially Management Board of Kirpart AS who made possible my PhD Study during my employment.

Special thanks and appreciation is to my wife Buket for her patience and prayers during my unceasingly endeavor.

Ahmet KUTLU

SYMBOLS and ABBREVIATIONS

Symbol	Definition
$^{\circ}\text{C}$	Celcius
cps/eV	counts per second per electron-volt
H	Enthalpy
keV	kilo electronic volts
kJ/L	kilojoule/liter
kJ/kg	kilojoule/kilogram : latent heat
λ	Thermal Conductivity (W/mK)
λ_{solid}	Thermal Conductivity at solid phase
$\lambda_{\text{sol/liq}}$	Thermal Conductivity at solid-liquid phase transition
λ_{liquid}	Thermal Conductivity at liquid phase
n	number of carbon atoms
$\mu\text{L/min}$	microliter/minute
Mv	Molecular weight
ρ	density
S(mm)	Stroke in millimeters
T($^{\circ}\text{C}$)	Temparature in Celcius
t(s)	Time in seconds
wt.%	Weight percent
w/v %	Weight /Volume percent

Abbreviation	Definition
2D	two dimensional
CT	Computer Tomography
DMF	N-N Dimethylformamide
DSC	Differential scanning chromatography
DTA	Differential thermal analysis
DTST	Dispersion thermal stability test
EDS	Energy-dispersive X-Ray spectroscopy
FTIR	Fourier transformation infrared spectroscopy
H	Enthalpy
NP	Nanoparticle
NF	Nanofiber
P/PAN	Paraffin/Polyacrylonitrile
PAN	Polyacrylonitrile
PCM	Phase Change Material
PVA	Polyvinylalchol
SEM	Scanning electron microscopy
SP/PAN	Solid paraffin/Polyacrylonitrile
TEM	Transmission electron microscopy
TGA	Thermo gravimetric analysis
TH	Thermal Hysteresis

1. INTRODUCTION

Emerging nanofiber production methods enable nanocomposite material production technologies which are exclusively compatible with their application areas for desired specific property enhancement. Methods of polymer nanofiber production with electrospinning will be emphasized in the next chapter. Method based nanofiber SEM images are inclosed under related topic, for more visualisation and recognition of the contributed utility provided by that technology.

Paraffin is widely used as thermal regulating material because of its exclusive properties including diverse melting temperatures, chemically inert and physically stable behaviors. On the other hand, because of its low thermal conductivity, researchers have focused on to enhance the thermal conductivity of paraffin by combining with other materials. Thermal properties of paraffin as a phase change material specifically related with paraffin actuators will be discussed in the next chapter in terms of theoretical basics and literature review.

The most important problem of paraffin actuators, which are used in a wide range of areas from automotive engine cooling systems to electronics and household appliances, is the paraffins poor thermal conductivity and therefore its poor thermal hysteresis behavior. In this thesis, the opportunity for thermal property improvement of paraffin as a phase change material in the industrial application area of paraffin actuators in terms of nanotechnological touch by nanofiber addition experimentally is evaluated.

Primarily the interaction between paraffin and nanofibers is assessed. Paraffin samples which have different number of carbons in their molecular chain with different melting points and electrospun polyvinyl alcohol nanofibers mat are investigated. Microscopic images revealed that liquid paraffin can be held on the surface on the nanofibers. Contact angle measurement results revealed that heptadecane has the highest and pentadecane has the lowest contact angle on PVA nanofibrous mat structures. As a conclusion, wettability of the nanofibers by liquid paraffin can be enhanced if the paraffin is used which has less number of the carbon atoms. Furthermore the examined

wettability of the electrospun nanofibers by paraffin, encouraged us working on development of a genuine method for facile production of paraffin-nanofiber hybrid system.

Accordingly a one-step preparation method of paraffin/polyacrylonitrile hybrid nanofibers via single needle (uniaxial) electrospinning system was invented. Solid paraffin with the melting point of 32°C nonadecane ($C_{19}H_{40}$), 58°C heptacosane ($C_{27}H_{56}$), 89°C tetratetracontane ($C_{44}H_{90}$) and 114°C hectane ($C_{100}H_{202}$) were employed for the preparation of the paraffin/polyacrylonitrile nanofibers. Formation of paraffin-nanofiber hybrid structure is verified with FTIR, DSC, TGA and SEM Analysis.

As-spun paraffin/polyacrylonitrile nanofibers with the molecular weight of were used for thermal hysteresis enhancement of paraffin actuators. Paraffin actuator sub-components are defined and its sample preparation is explained in terms of methods and materials. Paraffin compound of the paraffin actuators was prepared with a mixture of pure nonadecane paraffin. An eye kept on opening stroke behavior of the paraffin actuators while determining the paraffin-nanofiber weight ratio. Paraffin/Polyacrylonitrile nanofiber mixtures prepared with the wt. % of 2.5, 5, 7.5 and 10. The hysteresis value was successfully enhanced as 1.7, 3.4, 11.9 and 15.3% sequentially for the samples produced with the above ratios. Hysteresis enhancement of the paraffin actuator is discussed in terms of percolation threshold and thermal conductivity contrast effect theoretically.

Alternatively metal oxide microparticles and nanoparticles found use to improve thermal properties of paraffin in the paraffin actuators applications. A meaningful comparison between nanofiber addition and metal oxide nanoparticle addition was brought to light to examine the benefits of our development. Thermal hysteresis enhancement of paraffin actuators with nanofiber addition is compared with that of metal oxide nanoparticle. Nonadecane paraffin is used as the thermal expansion compound. Besides pure paraffin compound, paraffin mixed with the wt. % of 10 electrospun polyacrylonitrile nanofiber, CuO , Fe_3O_4 , ZnO , Al_2O_3 nanoparticles are

used as nanocomposites in paraffin actuator for thermal hysteresis enhancement. Literally interconnection between nanofibers lanes and mats built a thermal network in the composite structure. Those interconnecting hubs in nanoscale are appointed by SEM images. Despite lowest thermal conductivity value of the polymeric material, nanofiber addition showed through other metal oxide nanoparticle added samples, best hysteresis value improvement as 30.8 % respectively compared with pure paraffin.

Another comparison carried out to examine the long term thermal behavior enhancement of nanofiber addition and metal oxide nanoparticle addition to the paraffin actuators which is essential for the product life time determination. High temperature storage test is performed to investigate the dispersion thermal stability of the paraffin actuator samples. Due to considerably lower density of the nanofiber very close to that of paraffin, nanofiber addition showed the least precipitation in the paraffin matrix through other metal oxide nanoparticle added samples. Nanofiber added paraffin actuator sample revealed best dispersion thermal stability with a hysteresis performance loss of 2.2%. Computer tomographic images expressed the precipitation behavior of nanofiber and metal oxide particles which supported the thermal hysteresis performance change exactly same.

2. THEORETICAL BASICS and LITERATURE REVIEW

2.1. Electrospinning of Nanofibers

Nanofibers have fiber cross sectional diameter less than one micron, produced with different production methods. Properties of nanofibers are figured according to production process and used among a large application area from medical to aerospace technologies. Main nanofiber production methods can be listed as electrospinning, phase separation, drawing, self-assembly, electroblowing, template synthesis and centrifugal spinning. Through these methods of nanofiber production, electrospinning provides the most multipurpose process via the diversity of applied materials such as polymers, metallic and ceramic as well as composite structures produced directly or through post-spinning processes. (Teo and Ramakrishna, 2006)

Electrospinning technology depends on electrostatic spinning of polymer solution droplets in an electric field. In 1969 the mathematical model of electrospinning studied by Taylor and the conical shape of the fluid droplets which is called “Taylor cone”. (Taylor, 1969) Polymer solutions, which forms a Taylor cone under electrospinning process, are subjected to fabricate nanofibers in different diameters and size.

Many kind of synthetic or natural polymers as well hybrid structures are already electrospun from solutions, sol-gel suspensions or melts. Nanofiber morphology is affected by process parameters of electrospinning are applied voltage, distance of collector to capillary and flow rate of polymer solution. Solution parameters are affecting the nanofiber morphology which can be listed as polymer concentration, solvent volatility and solvent conductivity. Table 2.1 ,cited by Sill and von Recum's research, shows the relationship between these parameters and fiber formation. Nevertheless, the exact relationship must be considered individually for each polymer-solvent system. For the same polymer and electrospinning setup, it can be fabricated fibers with many different fiber formation depending on solution specifications. These are general frameworks useful for defining the optimum parameters for a individual system (Sill and von Recum, 2008)

Table 2.1. Morphology of fiber affected by electrospinning parameters (Sill and von Recum, 2008)

Parameter	Effect on fiber morphology
Applied voltage ↑	Fiber diameter ↓ initially, then ↑ (not monotonic)
Flow rate ↑	Fiber diameter ↑ (beaded morphologies occur if the flow rate is too high)
Distance between capillary and collector ↑	Fiber diameter ↓ (beaded morphologies occur if the distance between the capillary and collector is too short)
Polymer concentration (viscosity) ↑	Fiber diameter ↑ (within optimal range)
Solution conductivity ↑	Fiber diameter ↓ (broad diameter distribution)
Solvent volatility ↑	Fibers exhibit microtexture (pores on their surfaces, which increase surface area)

Different types of Electrospinning process are developed for fabrication of specific fiber structures. These can be sorted as Solution Based Electrospinning, Gas-Jacket Electrospinning, Melt Electrospinning, , Needleless Electrospinning ,Bubble Electrospinning , Magneto Electrospinning ,Conjugate Electrospinning, Centrifugal Electrospinning , Co-axial Electrospinning.

2.1.1. Solution based electrospinning

At the basic electrospinning process, the polymer solution droplet in a plastic syringe is pressed into the syringe needle by hydraulic pressure, where the droplet is subjected a strong electric field. The strong electric field intensed on the droplet surface and formed a cone-like surface shape which is called as the Taylor cone (Taylor, 1969). As soon as the electrical field overtakes a limit value, the electrical forces exceed the polymers

droplets surface tension and a nanoscaled polymer solution jet flow begins. Electrically charged jet accelerates elongates and reduces the polymer diameter to under micron scales. Solidification occurs through evaporation of the solvent by strong ventilation. Nanofibers randomly lay on the collector surface and assemble a thin layered nonwoven structure. Applied voltage is as high as 20-100kV. Distance of needle tip and collector is between 10-25cm in the spinning set-up (Greiner and Wendorff, 2007). Solution based electrospinning effected by interfacial viscosity of streaming solution within air, viscosity of polymer solution, electrostatic repulsion force acted on liquid solution, applied voltage, needle to collector distance, ambient temperature as illustrated in Figure 2.1. (Pelipenko et al., 2013)

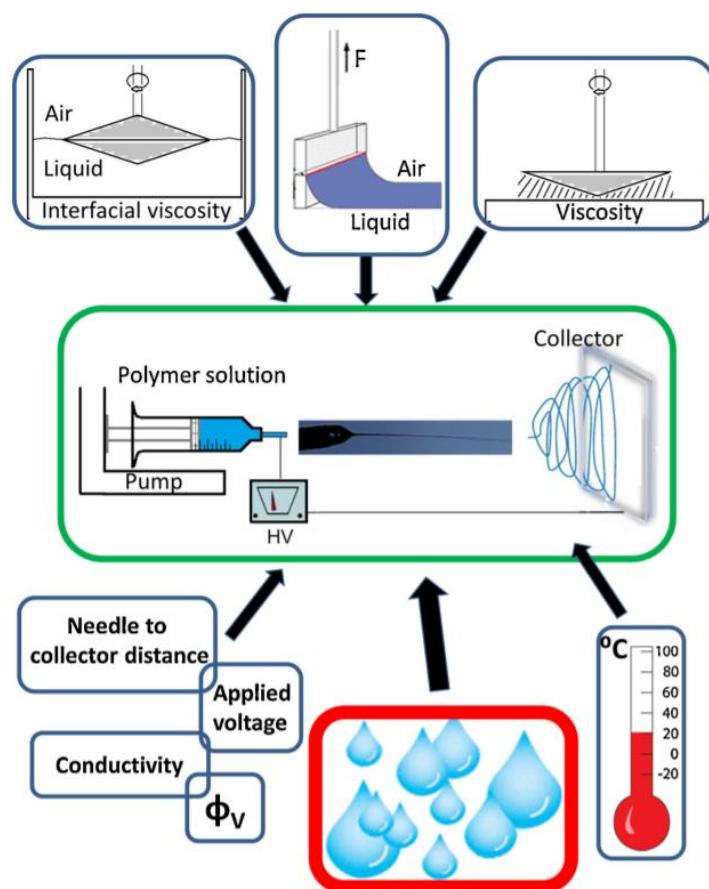

Figure 2.1. Electrospinning process schematic representation , with parameters influences the electrospun product morphology. (modified from source: Pelipenko et al., 2013)

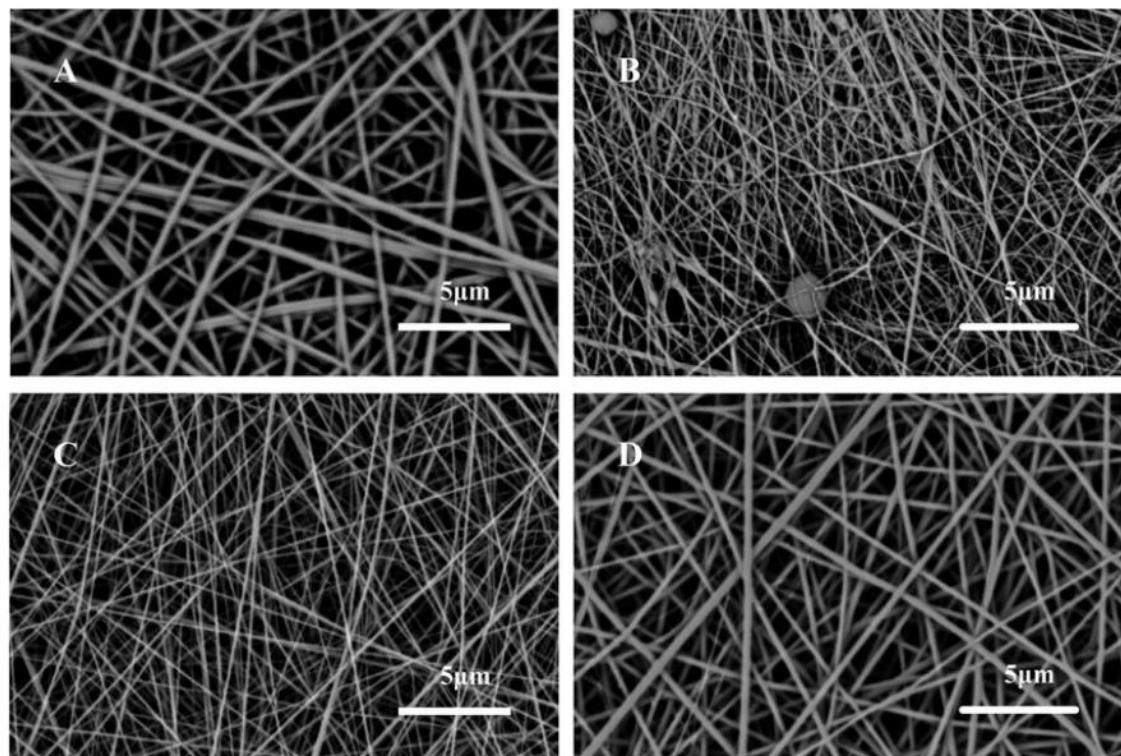

Figure 2.2. PAN nanofibers SEM images (A) and different concentration electrospun PAN-AA nanofibers of (B) 6 wt%, (C) 8 wt%, and (D) 10 wt%. (Yang et al., 2017)

Figure 2.2 demonstrates the nanofibers produced by solution based electrospinning process with different solution concentrations , as well viscosity where obviosly dependence of the nanofiber diameter to the viscosity is visible. (Yang et al., 2017)

2.1.2. Melt electrospinning

Polymer melts can also be used for nanofiber production via electrospinning. The main advantage of the melt electrospinning is avoiding from solvent chemicals and using temperature to feed the liquid polymer to electrospinning zone. Viscoelastic behavior of molten polymer forms the Taylor cone on the end of spinneret at a specific voltage level and nanofiber spinning starts when the electrostatic loading exceeds the surface tension of polymer droplet. Even environmental and safety requirements commit non-chemical solvents usage, melt electrospinning is used for limited applications. Rheology of molten polymer which is directly affected by the small deviations of heat supply obstruct the continuous production of nanofiber with same quality. (Lyons et al., 2004)

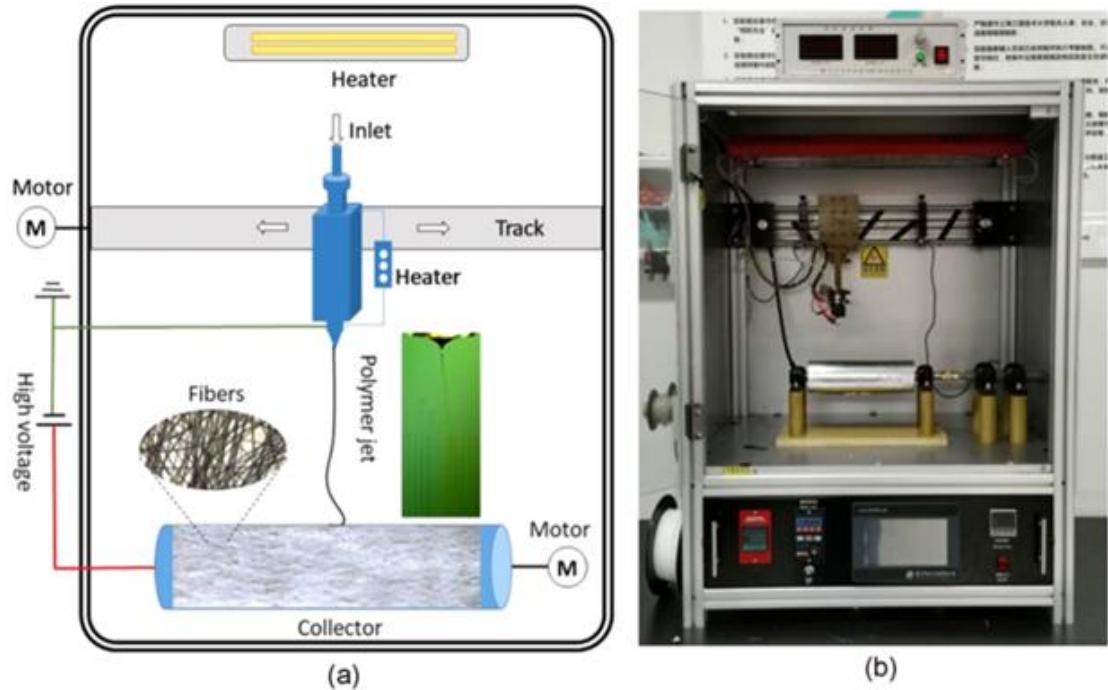

Figure 2.3. Melt Spinning- (a) Schematic Diagram and (b) picture of experimental device setup . (Mu et al., 2021)

Mu et al. investigated on factors acting on melt electrospinning process. Figure 2.3 shows the schematic diagram and the device picture of the mentioned investigation. Pellet-like Polypropylene was used as the polymer material. Temperature had an important effect on jet motion and Taylor cone. High voltage application caused to an electric field load on the droplet and a high speed jet formation occurred. Taylor cone size was smaller at that sample with at 220°C than that of 300°C. However more obvious whipping jet observed. It can be declared that different temperatures affected the viscosity and surface tension of molten polymer which influenced to the blowing of the jet and the Taylor cone's initial shape . This resulted changes in nanofiber diameter, structure and morphology.

In Mu's investigation temperature effects on fiber diameter is studied and various positions are used for observation of the fiber morphology. Temperature of nozzle heating has a magnificent effect on the fiber diameter and the orientation of fiber.

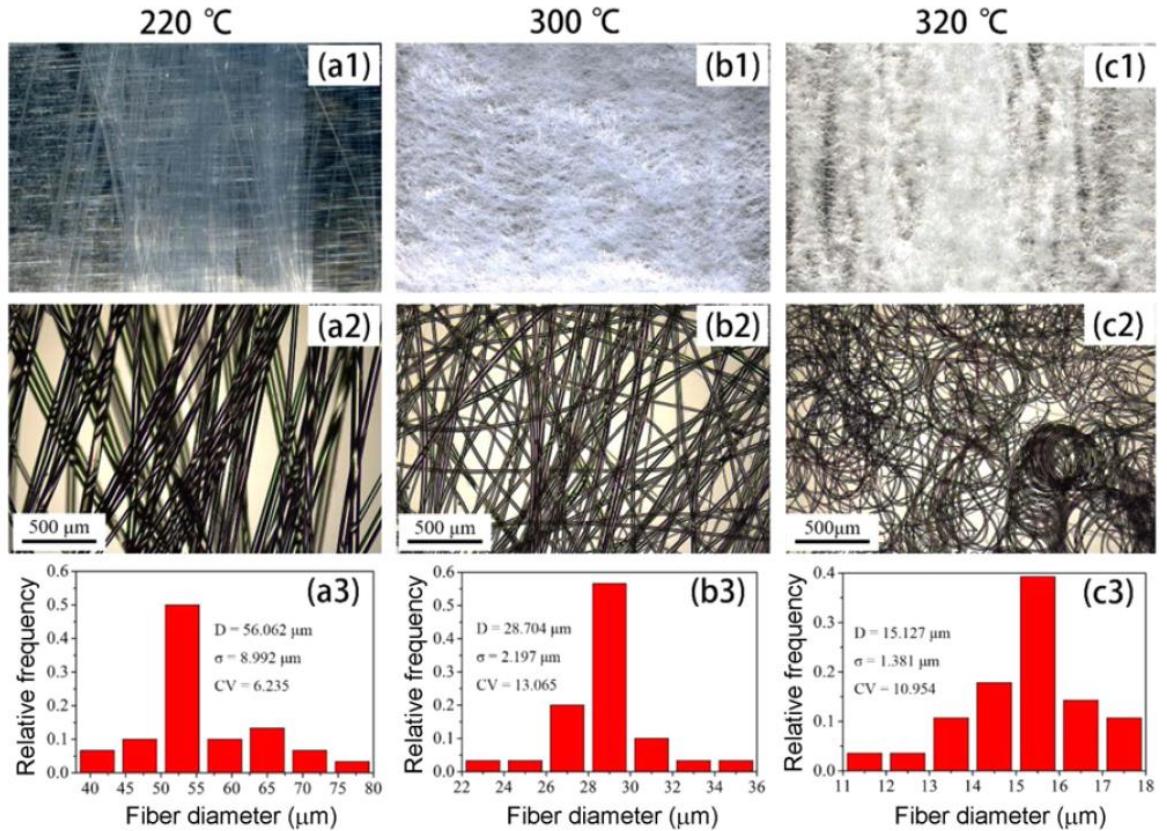

Figure 2.4. Fiber mats microscope images , with the temperatures of 220 °C, 300 °C, 320 °C; (a1, c1) melt-electrospun microfiber mats images, (a2, c2) melt-electrospun fibers images, and (a3, c3) melt-electrospun microfibers diameters. (Mu et al., 2021)

Temperature increase changed the fiber shape enormously. Parallelly oriented fibers are observed at 220 °C with uniformly distribution. At 300 °C, curly and wavy patterned fibers with alignment in horizontal and vertical directions revealed as seen in Figure 2.4. Fiber crystallinity is affected directly from temperature where at 220°C 42,59%, at 300°C 41,71% and at 320°C 36,60% crystallinity is measured. Mu concluded from the data that as the temperature increases, the fiber crystallinity degree decreases where it can be explained as the polypropylene's molecular chain of polypropylene is weakened at an over temperature, decreasing the crystallinity. On the other hand mechanical properties of the fiber is dramatically affected by temperature change where breaking strength decreased from 13,87MPa to 0,80MPa with the temperature increase from 220°C to 320°C. (Mu et al., 2021)

2.1.3. Gas-jacket electrospinning

Some polymer types are difficult to process in electrospinning by lack of insufficient forces based on electrical voltage. A special force source must support the electrospinning forces to boost the jet flow formation of polymer solution. An inert gas flow is used to execute a gas jacket around the spinneret tip.

Polyacrylic acid nanofibers were produced by the gas-jacket electrospinning technic by Aminyan and Bazgira. Figure 2.6 shows the diagram of the gas-assisted electrospinning of the research. They declared that gas-assisted method provides flawless and more regular fibers compared to the conventional electrospinning. In different ratios of NaOH 0, 15, 30 and 45% was used for the neutralization improving the spinnability and fiber properties. SEM micrographs revealed that increasing neutralization have an effect on swelling ratio with 30% neutralization. Increasing of feeding rate affected also swelling ratio as decreasing where optimal feeding rate was 20 $\mu\text{L}/\text{min}$. Increasing Polyacrylic acid concentration, decreased the ratio of swelling, with an optimal value of 9 wt% solution.

Figure 2.5. shows two nanofiber PLA electrspun nanofibers, left side conventional as-melt electrospun and right side gas assisted system applied where depending on the deformation through the hot gas stream, fibers with sub micron diameters can be produced with melt-electrospinning as seen in the figure. (Zhmayev et al,2010)

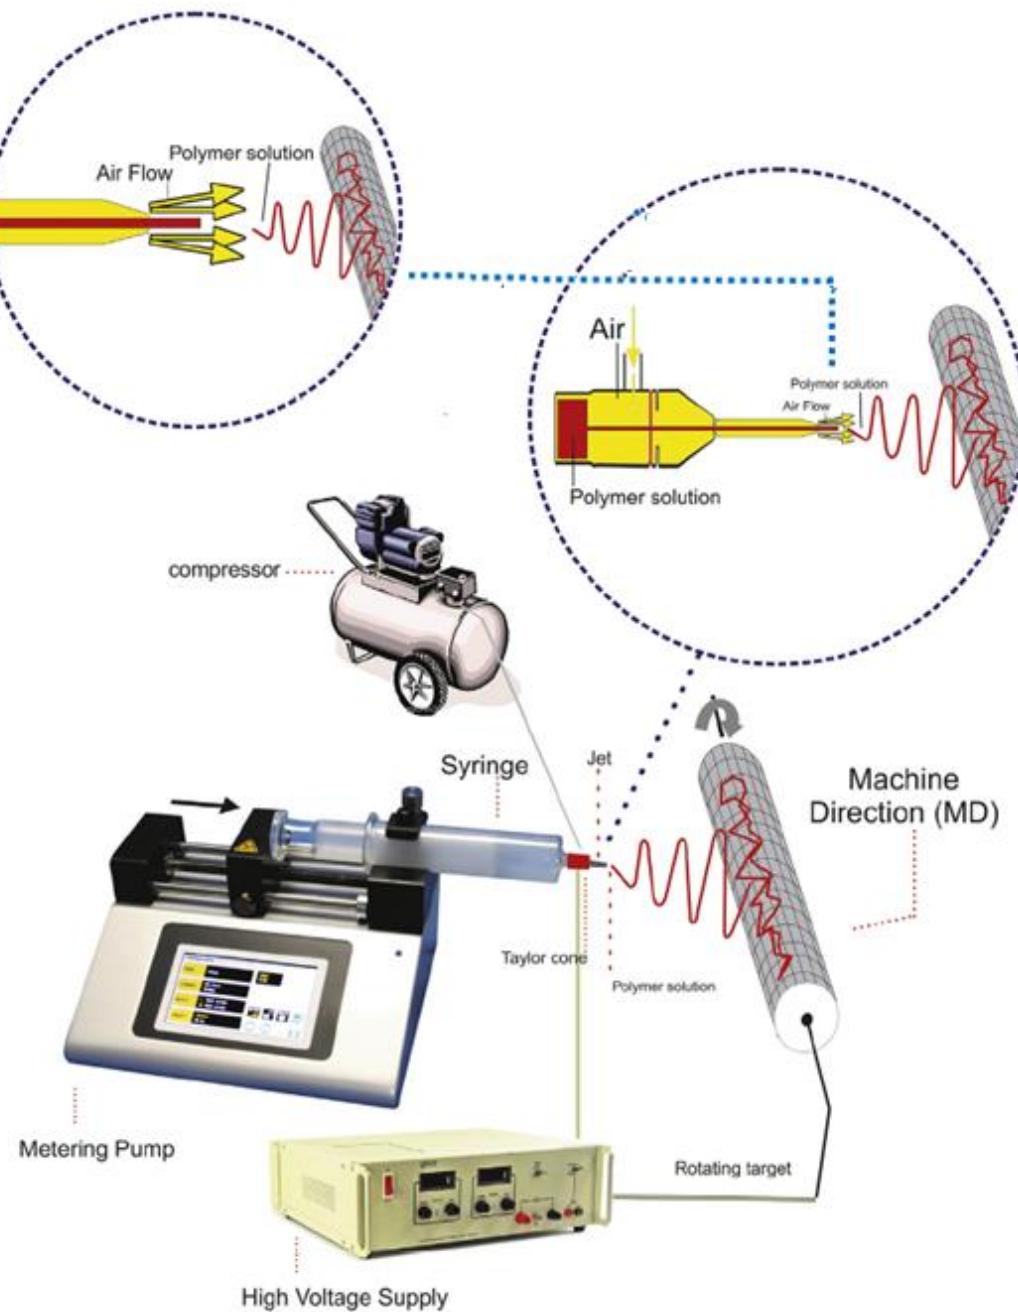

Figure 2.6. Gas-assisted electrospinning system. (modified from source: Aminyana and Bazgira, 2019)

2.1.4. Bubble electrospinning

Bubble electrospinning uses an electric field charged to the polymer bubble surface, which quickly loosens on the bubble surface. As soon as the electric field exceeds the critical value needed to exceed the surface tension, the bubble ruptures and the broken bubble is pushed

upward to form a charged jet, which is then received as nanofibers on the metal receiver. (Zhao et al. 2015)

Figure 2.7 shows an example for a bubble electrospinning setup made by Liu and Friends, which includes DC high-voltage generator, flat metal plate grounded as collector, reservoir of solution, a gas tube, a gas pump, a metal thin electrode. (Liu et al. 2015)

Nanofiber are collected as randomly oriented non-woven form at Bubble-Electrospinning. This causes low molecular orientation as well as low mechanical properties. Low molecular orientation was caused by randomly oriented nanofibers. Shao and friends investigated on bubble electrospinning to modify it and placed a positively charged ring between parallel electrode collector and the bubble and for improving the nanofiber alignment degree. The results showed nanofiber diameter is decreased by the modification decreased, the diameter distribution and alignment of nanofiber is improved. (Shao et al. 2018)

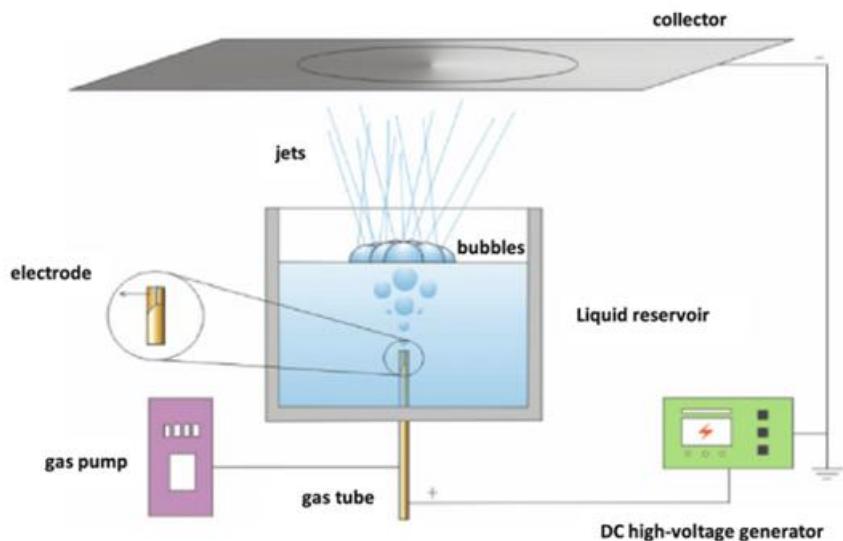

Figure 2.7. Bubble electrospinning setup (Liu et al. 2015)

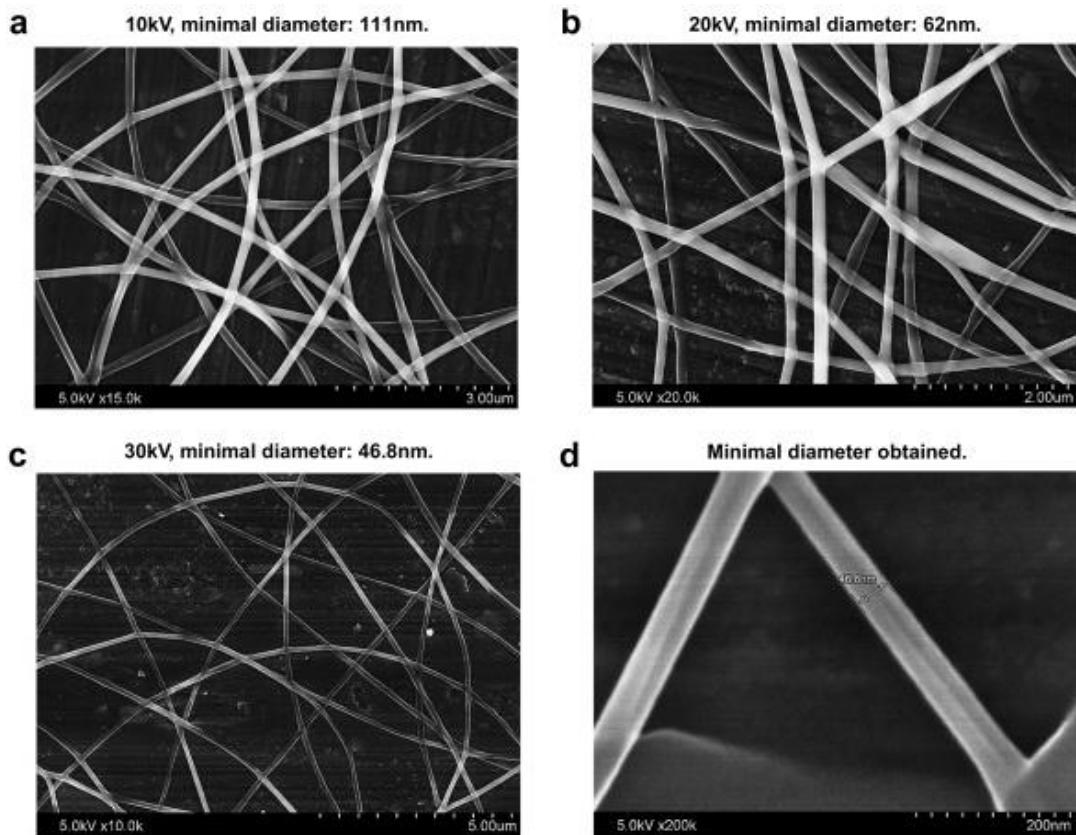

Figure 2.8. Distribution of fiber diameter size and SEM images of bubble-electrospun nanofibers. Applied voltages (a) 10 kV, (b) 20 kV, (c) 30 kV. (Yang et al. 2009)

Bubble-electrospun nanofibers produced by Yang et al. with three different voltages, from 8mm nozzle distance to the collector as shown in Figure 2.8, different nanofiber diameters generated at 10 kV, diameter minimum: 111 nm., 20 kV, diameter minimum: 62 nm. And, 30 kV, diameter minimum: 46.8 nm. (Yang et al. 2009)

2.1.5. Magneto electrospinning

Magneto Electrospinning of polymers based on magnetic nanoparticle embedded polymers. Aluminum foil is subjected to a magnetic field. The magnetic field is parallel to the electric field and perpendicular to collector in the system as shown in Figure 2.9. (Kartikowati et al., 2016) Magneto electrospinning has potential application areas like tissue-engineering scaffolds, magnetic filters, magnetic sensors, electromagnetic wave absorbers, microwave absorbers (Park et al., 2009), magnetic catalysts (Ghasemi et al.,

2015),, magnetic hyper thermia (Kim et al. 2013) and ferroelectric photovoltaic devices (Fei et al. 2015)

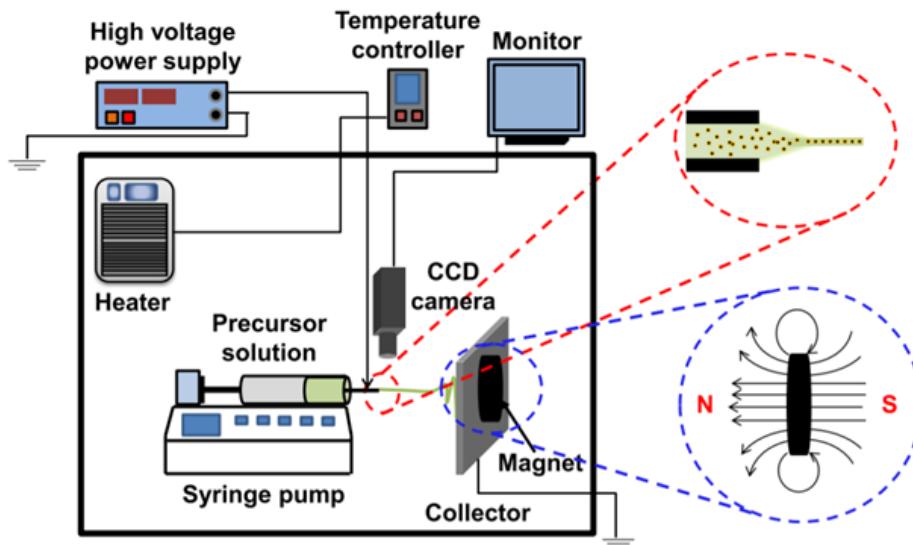

Figure 2.9. Magneto-electrospinning setup (Kartikowati et al., 2016)

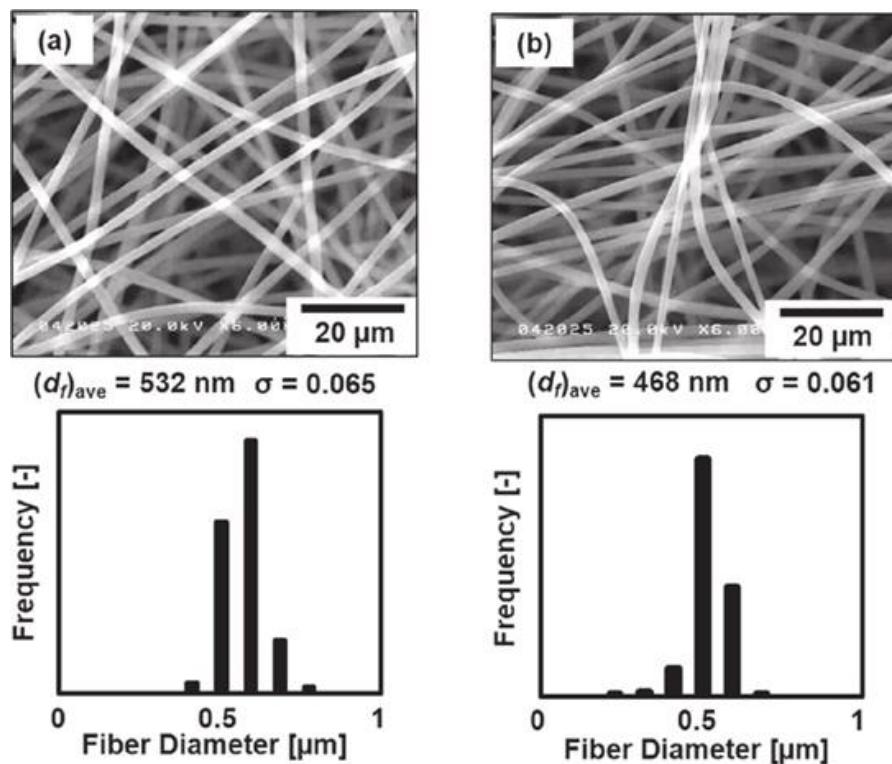

Figure 2.10. PVP nanofibers size distribution and SEM images without magnetic field (a) and with magnetic field (b) (Kartikowati et al., 2016)

Figure 2.10 demonstrates the PVP nanofibers SEM images and diameter distribution of Kartikowati's study. Magnetic field applied nanofibers have lower diameter, revealing a distribution with a lower standard deviation.

2.1.6. Conjugate electrospinning

At conjugated electrospinning two different solutions containing one oxidant and the other one reductant solution turns into nanofibers via two branch electrospinning method under a curing reaction mechanism. The opposite charges coupled these electrospinning jets. Active monomers are polymerized in the presence of free radicals produced in situ from a redox reaction that the jet containing oxidant met to the jet containing reductant. This process finalized as solidification of nanofibers from the conjugated jets. Figure 2.11 illustrates the electrospinning equipment and conjugated jet pictures from the experimental setup of Wang's study. (Wang et al. , 2019)

Fan et al. fabricated a polyaniline- polyacrylonitrile using the conjugate electrospinning based on microyarns simultaneously endowed with electrical conductivity .The hetero-structured microyarns had twisted structure and highly oriented fibers. The hetero-structured microyarns improved luminescent properties. (Fan et al., 2019)

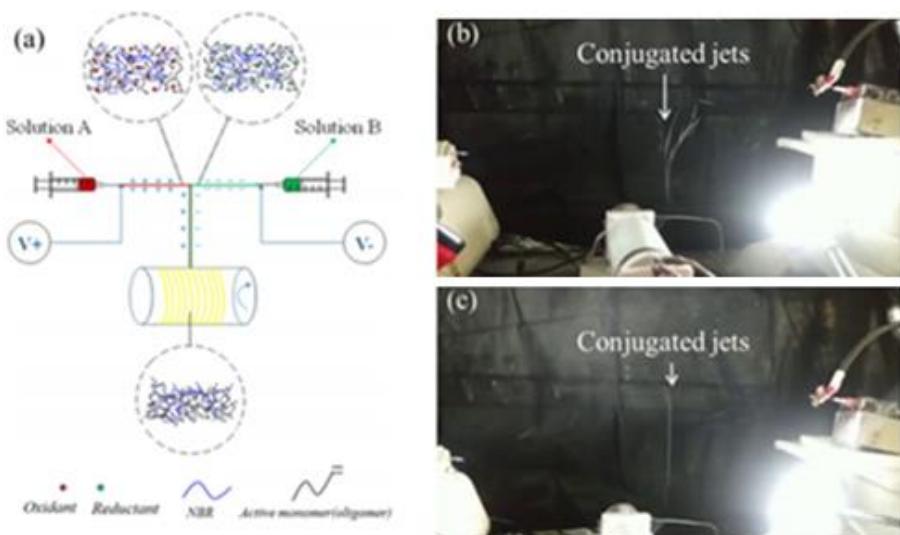

Figure 2.11. (a) Conjugate reaction e-spinning system and pictures (b, c) of conjugate electrospinning process (modified from source: Wang et al. ,2019)

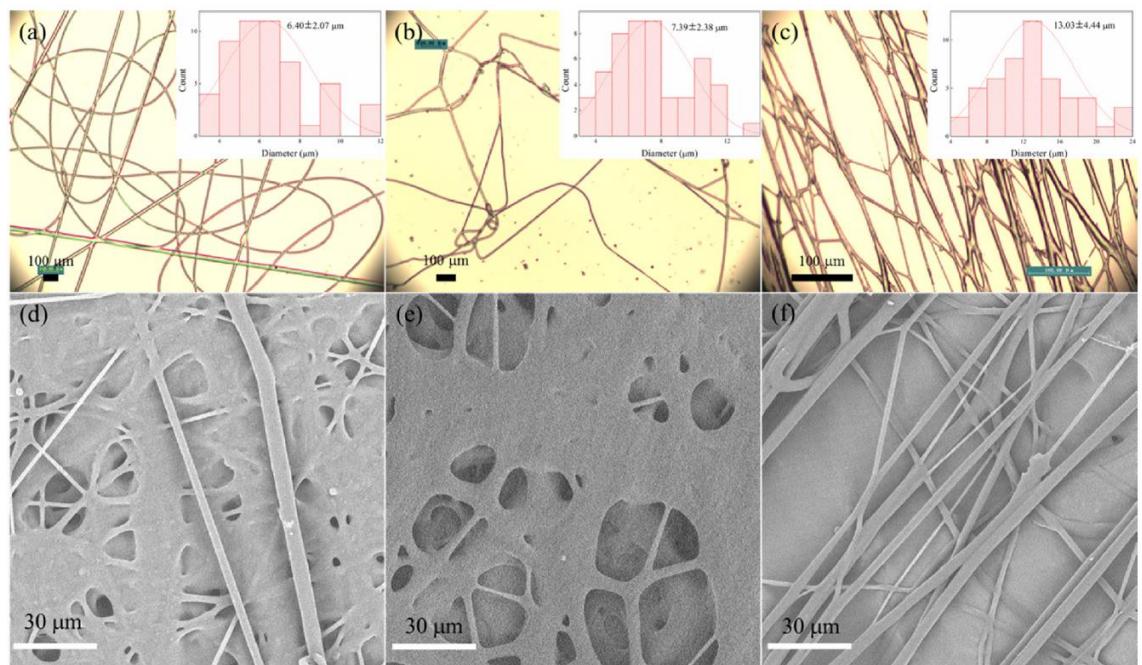

Figure 2.12 (a, b) Optical images of electrospun fibers of A and B single, as well as one (c) of A/B conjugated electrospun fibers soon after electrospinning. (d–f) SEM images of single A, B and conjugated A/B electrospun fibers 48 h after electrospinning process, respectively. (a),(b) and (c) Inset images are the diameter distributions of the as-spun fibers. (Wang et al. , 2019)

Figure 2.12 demonstrate the conjugated and non-conjugated nanofibers SEM images from Wang's study. (Wang et al. , 2019)

2.1.7. Co-axial electrospinning

Coaxial electrospinning consisting two capillaries which are coaxially arranged . The composite droplet forms a composite Taylor cone is formed by composite droplet where the core polymer and shell polymer are pulled by Taylor cone. The shell polymer and core polymer are attracted to the Taylor cone of the composite droplet. The nanosized polymers are drawn by the electrospinning beam and collected on the fiber mat collector. (Reznik et al., 2006).

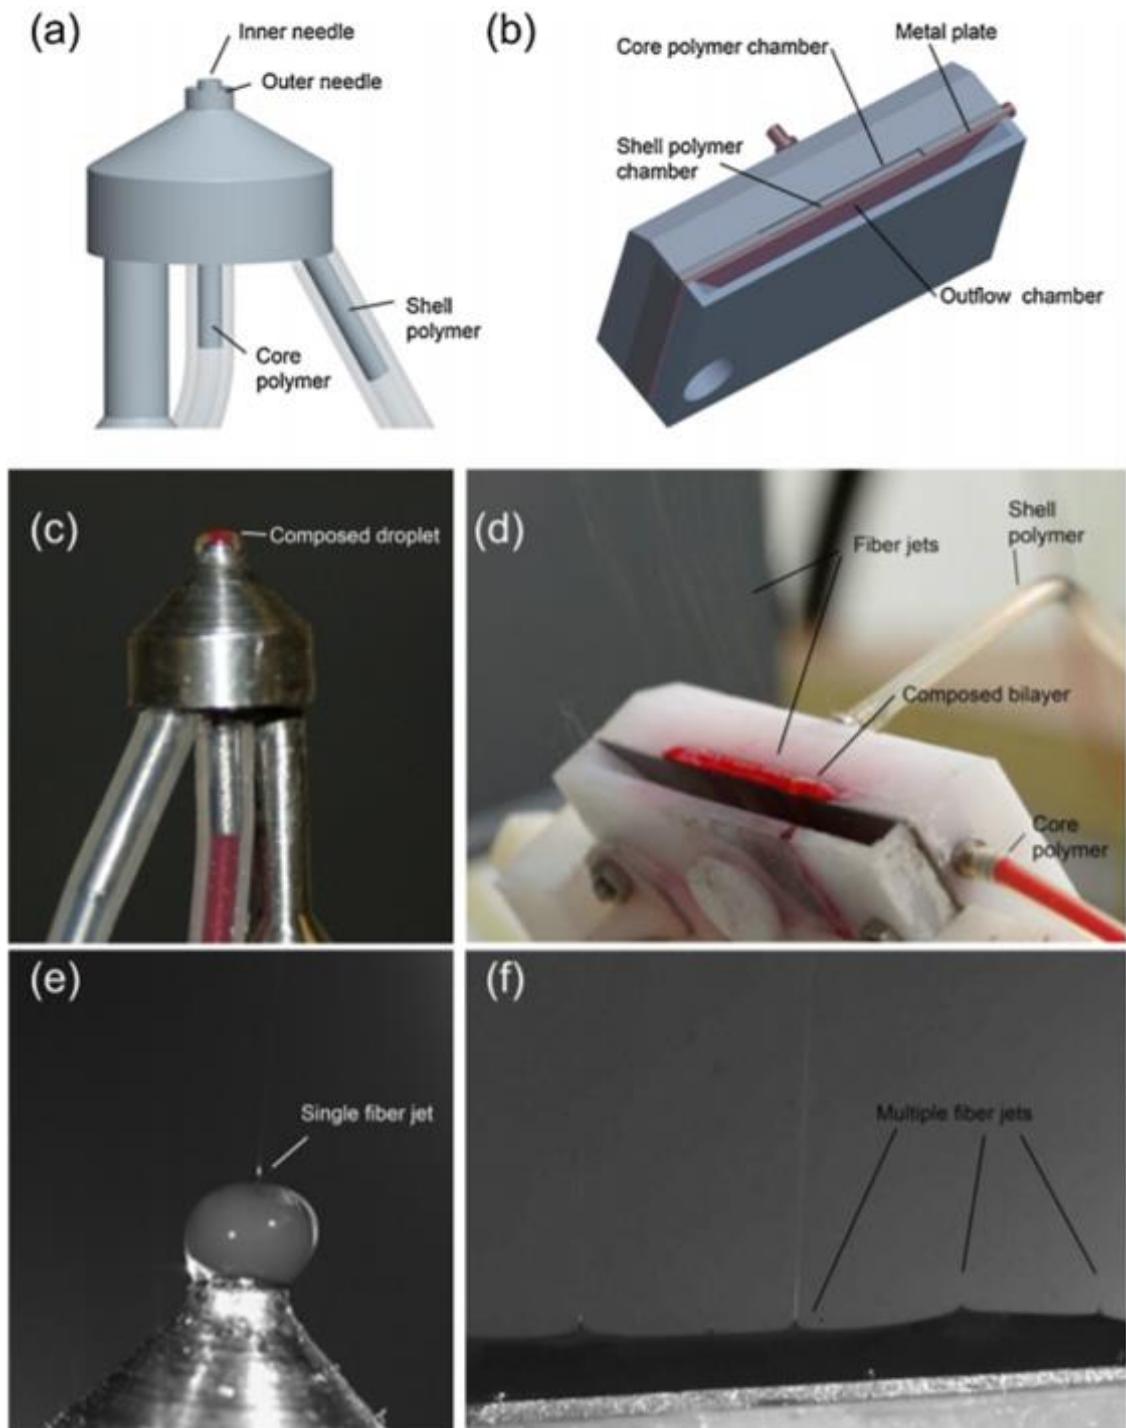

Figure 2.13. Coaxial electrospinning: (a) coaxial spinneret with needle, (b) coaxial (weir) spinneret without needle, (c) polymeric droplet of coaxial needle spinneret , (d) polymeric bilayer of coaxial spinneret without needle, (e) polymer droplet of coaxial spinneret with needle , highspeed camera image, and (f) bilayer of coaxial spinneret without needle, high-speed camera image. (Vyslouzilova et al.,2017)

Vyslouzilova et al. investigated on the special spinneret for large amount coaxial nanofibers production. Figure 2.13 demonstrates its co-axial spinneret equipment set-up. On the top of linear spinneret, bi-liquid layer is formed by the spinneret where formation of coaxial nanofibers enabled by electrospinning without needle. Production capacity of fibers increased by the fiber's core/shell morphology. (Vyslouzilova et al.,2017)

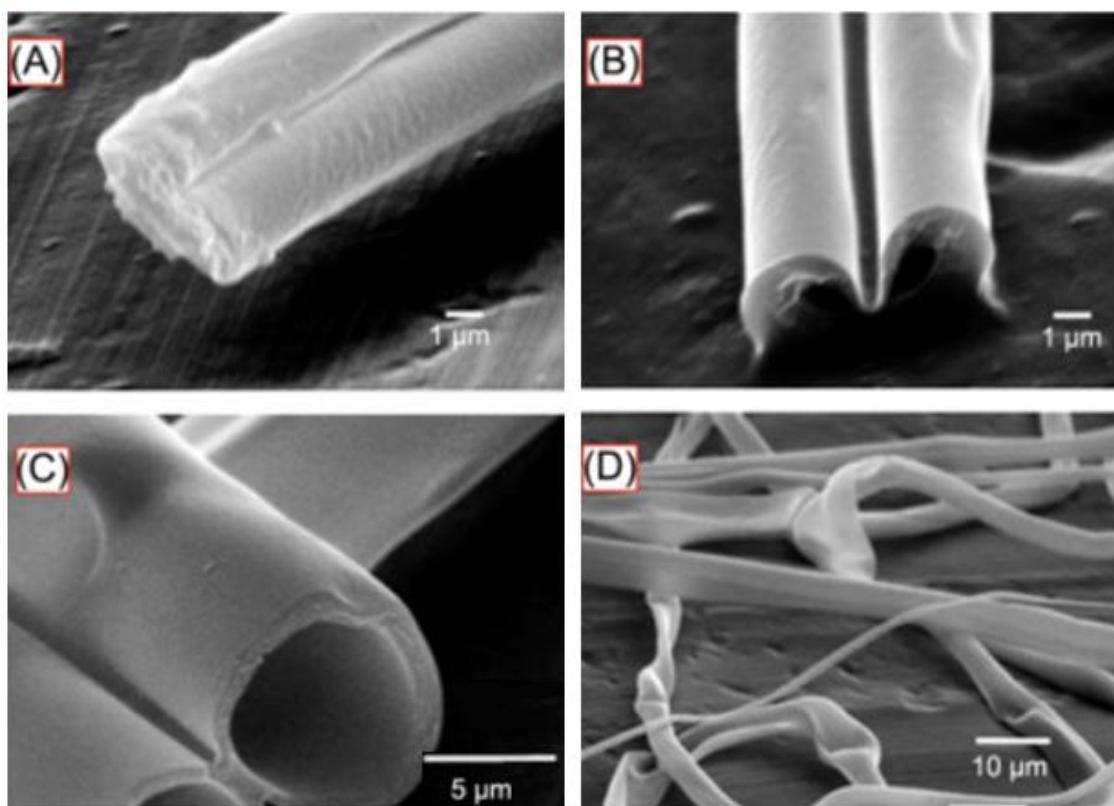

Figure 2.14. Coaxial electrospun, ID = 0.8/2.5 mm (core/sheath), SEM images of etched PMMA 20 wt% PMMA sheath solution with 1 mL/h feed rate, feed rates of mineral oil (A) 0.10 mL/h, (B) 0.40 mL/h, (C) 0.60 mL/h, and (D) 1,0 mL/h, (Chan and Kotaki, 2009)

Figure 2.14 depicts the relationship between morphologies of hollow fiber and feeding rates of core studied by Chan and Kotaki . The optimum feeding rate was 0.6 mL/h for production of structures with hollow form. Increase in feeding rate of core was changed morphology is gradually. (Chan and Kotaki, 2009)

2.1.8. Needleless electrospinning

Classical needle electrospinning has limited production capacity. Many investigations afforded to improve the productivity of electrospinning process. Needleless electrospinning technology was subject of many research thus production with multiple jets meant to enhance the nanofiber production efficiency significantly.

Wei et al. investigated on needleless electrospinning with a system consisting of a control pump of solution , spinneret made of metal dish, collector rotating system , a moving platform, spinneret base, power supply of DC high voltage. The insulating tube is connected with a hole to polymer solution in middle of spinneret. Feeding pump was set in center of the insulating tube which is used to transfer the solution to the spinneret. As soon as a certain radian is reached by the solution, polyacrylonitrile solution is passed the metal dish. Figure 2.15 shows the new electrospinning device without needle for fabrication of nanofiber membranes . The device includes a temperature / humidity control system ,an unwinding system , a metal plate nozzle, rotating roller collector, a cross control system, and a high-voltage DC power supply. For industrialization, high quality nanofiber membranes can be produced with high efficiency. Surface morphology, pore diameter, filtration properties and stress-strain depending on main spinning parameters were investigated. A similar trend between filtration resistance and filtration efficiency revealed by results . Low resistance of filtration and high efficiency of filtration were 140 Pa and 94% , respectively. (Wei et al., 2021)

Mikes et al. used needleless electrospinning for facile production of lignin nanofibers. As the electric field source AC and DC and systems tested electrospinning without needle setup. Polymer dosing and fiber collection was complicated at DC needleless system where the AC electrospinning was more compatible technology in terms of for large-scale productions in future works. (Mikes et al., 2020)

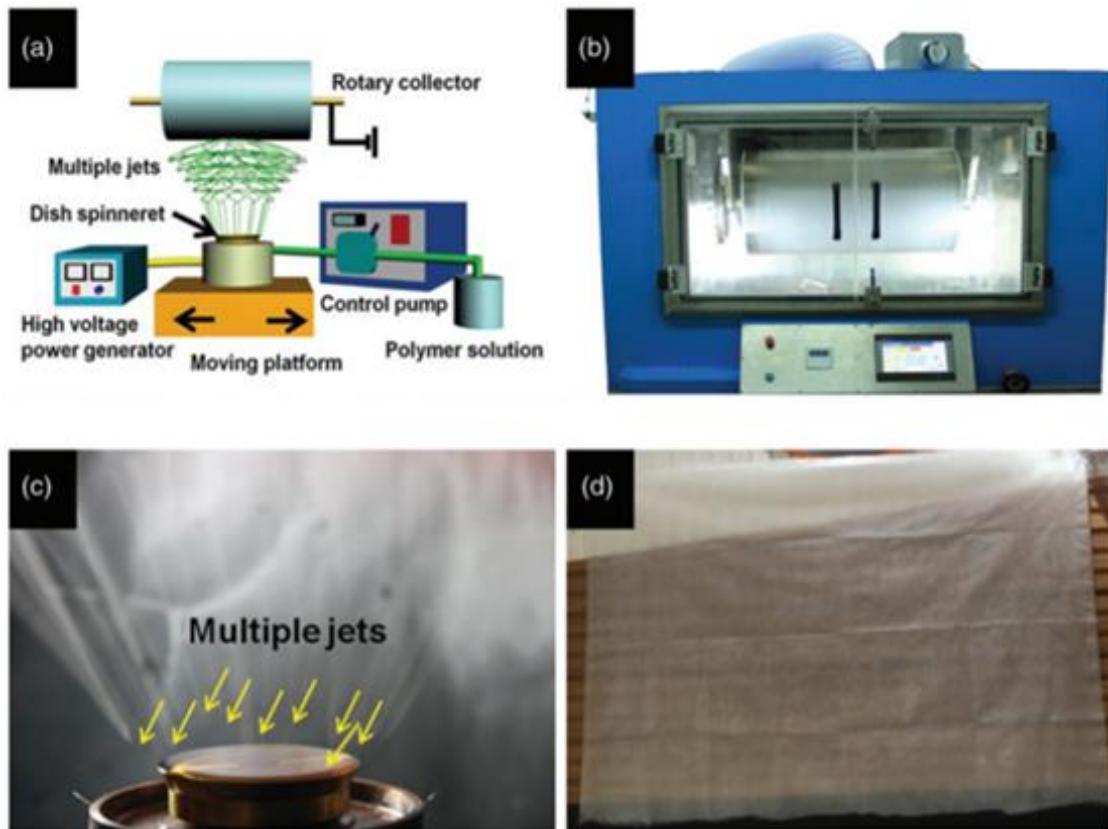

Figure 2.15. (a) and schematic map (b) setup of electrospinning without needle (c) multiple jets images and (d) membrane made of nanofiber. (modified from source: Wei et al., 2021)

Figure 2.16 shows visual results of electrospinning parameters; voltage and concentration effecting on the nanofiber morphology with the 15cm collecting distance at needless electrospinning with multiple-jet. Applied voltages and solution concentrations are grouped in three different values for the nanofiber fabrication. Obviously that finer nanofibers could be fabricated with higher voltage and lower concetration value (65 kV, 10 wt %). Thicker nanofiber morphology observed, compared with higher solution concentrations of polymer and with lower the voltage supply. (Wei et al., 2021)

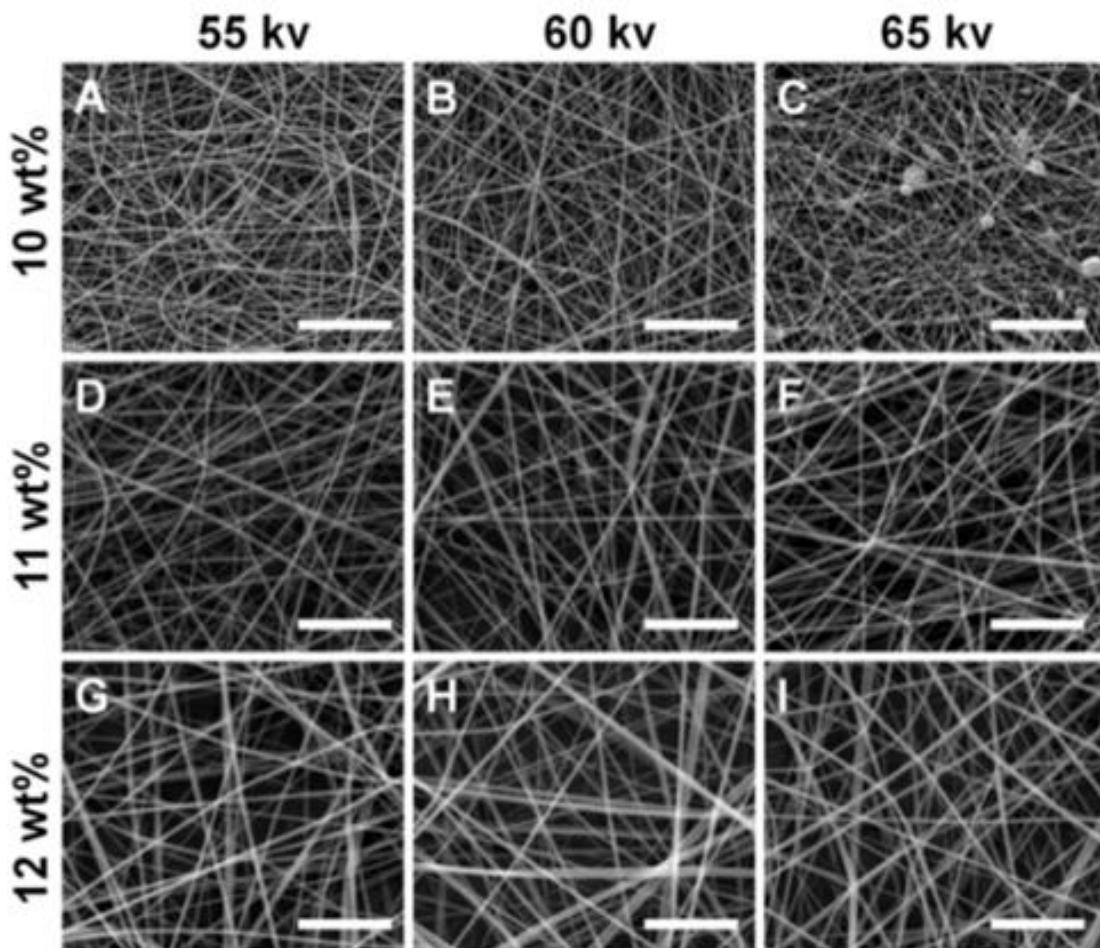

Figure 2.16. Different conditions of the spinning process used for nanofiber production. Scale bar : 5 μm (A) 10 wt %, 55 kV, (B) 10 wt % 60 kV, (C) 10 wt, 65 kV (D) 11 wt %, 55 kV (E) 11 wt %, 60 kV (F) 11 wt %, 65 kV (G) 12 wt %, 55 kV, (H) 12 wt %, 60 kV (I) 12 wt %. 65 kV. (Wei et al., 2021)

2.1.9. Centrifugal electrospinning

Centrifugal electrospinning comprises a collector and an electrospinning rotating spinneret which consist of compartments for solution; with two channels for hosting of media. Wang et al. presented a directional advance in multi- aligned fibers using multiple compartments and in engineering blended fibers where centrifugal and electrical forces issued for spinning process shown as in Figure 2.17. A combination of Polystyrene and Polyvinyl Pyrrolidone polymers was investigated where the system meant to be practicable to viscoelastic polymeric materials. (Wang et el., 2017)

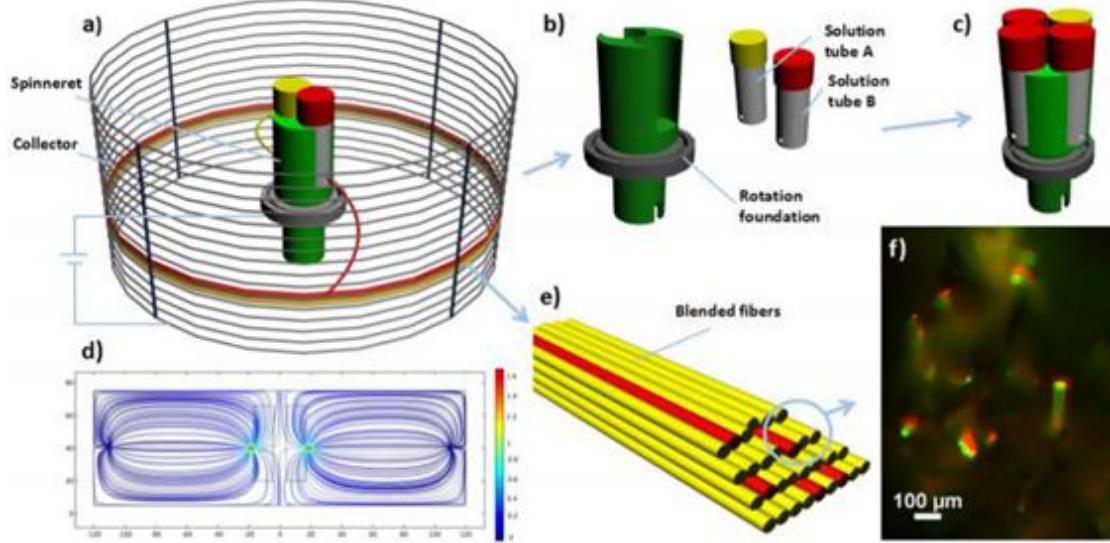

Figure 2.17. Centrifugal electrospinning system setup and fibers produced. (a) Centrifugal electrospinning system with combinatorial multi-compartment system-Schematic setup. (b) Two compartments detached spinneret . (c) Four compartments hosted by spinneret (d) Two individual jets - computational detail under an applied electric field. (e) Composite material illustration (f) Polyvinylpyrrolidone blended system in fluorescent micrograph (Wang et el., 2017)

Hofmann and Kühne presented a productive method for PAN nanofiber nonwovens fabrication with centrifugal electrospinning where the parameter range for producing sub-micrometer sized nanofibers in a nonwoven membrane is established. (Hofmann and Kühne, 2021)

Rihova and friends studied on a cost effective centrifugal electrospinning method represented in Figure 2.18. where scanning electron microscopy images obtained from Polyvinylalcohol and Polyvinylpirollidone electrospun fibers with different polymeric concentrations. SEM images showed a smooth surface of fiber without visible defects, such as droplets, beads, cracks other imperfections upto 20 wt. %. On the other hand , Polyvinylpirollidone (10 wt. %) contained beads caused by low concentration. (Rihova et al., 2021)

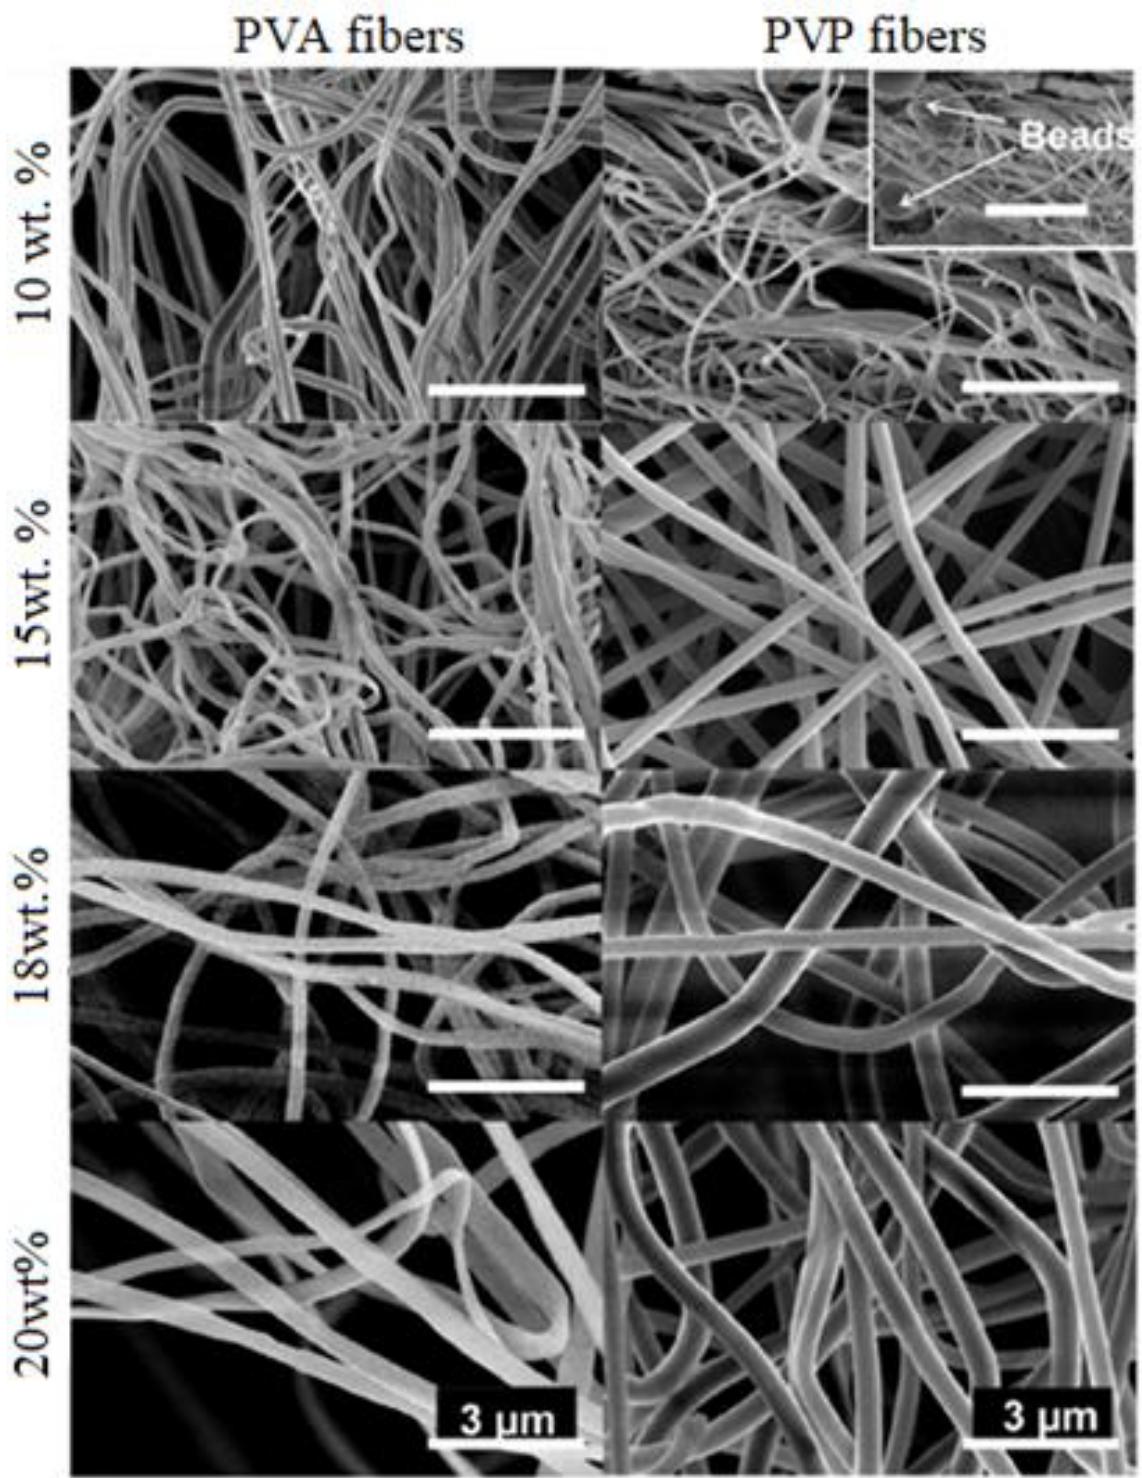

Figure 2.18. Electrospun fibers produced by the special 4SPIN® tool, SEM Images (scale bar: 3 μ m) (Rihova et al., 2021)

2.2. Paraffins as Phase Change Materials

2.2.1. Phase change basics

Phase-change materials, defined by Fleicher as materials which shows a solid to liquid and liquid to solid phase transition at a temprature, better known as the melting-solifiying cycle, within a selected thermal applications operating range. When a material changes its phase from solid to liquid, it absorbs thermal energy from its environment while keeping a constant or nearly-constant temperature. The energy absorbed by the material increases the energy of composing molecules or composing atoms and increases their vibrational state. At the melting temperature, atomic bonds are loosen and the material turns from solid to liquid. Reversion of this process is solidifcation, in which the liquid material exposes energy to its environment and the molecules and atoms lose energy and forming into their solid phase. (Fleischer, 2015)

In the last few decades , energy storage materials, including paraffins, eutectic mixtures of organic and inorganic compounds, hydrated salts, fatty acids are subjected to many investigations .Researches on phase change materials are basically focused on thermal energy storage where various material types have been examined previously. Figure 2.20 shows range of melting enthalpy and melting temperature for the certain materials. (Cabeza et al., 2011)

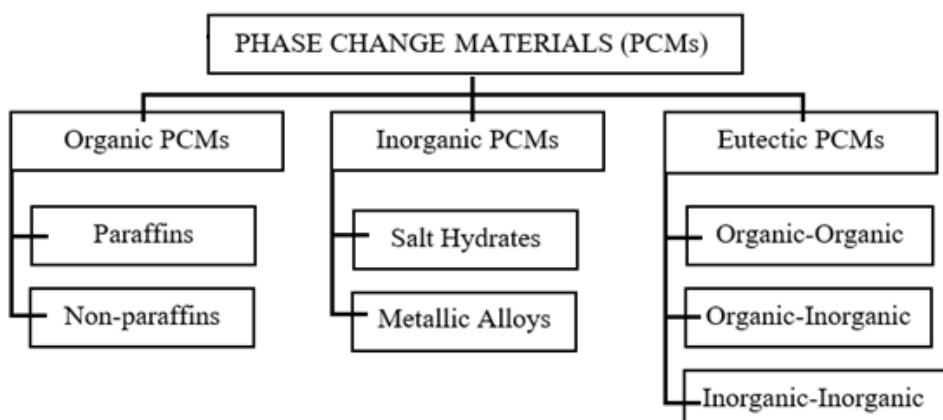

Figure 2.19. Scheme of phase-change material classification (Kapsalis and Karamanis,2016)

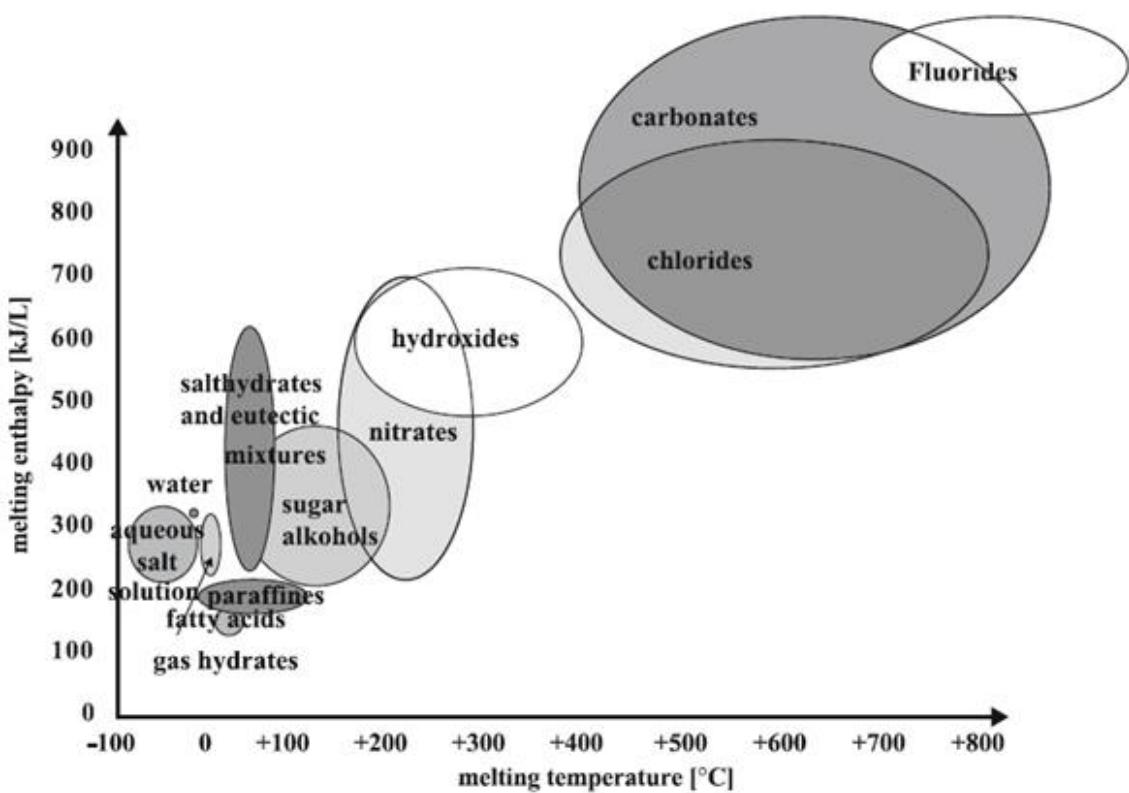

Figure 2.20. Material classes applicable as phase change material regarding to specific melting enthalpy and melting temperature range (Cabeza et al., 2011)

Classification of phase change materials can be noticed according to their content eutectic, inorganic and organic. Figure 2.19 demonstrates the classification of phase change materials. Inorganic materials have a larger temperature range and usually density over 1 g/cm^3 and have higher melting enthalpy organic phase change materials. Organic materials have mostly density smaller 1 g/cm^3 and lower melting enthalpy. Mixture of organic and inorganic phase change materials also investigated to cover the advantages of both classes. Organic phase change materials are consist of paraffins and non-paraffins. Energy storage materials can be categorized into two groups organic and inorganic according to their composition. Further two subcategories can be used as eutectic and mixed temperature ranges. (Kapsalis and Karamanis, 2016)

2.2.2. Paraffins

Paraffins belong to organic phase change materials besides sugar alcohols and fatty acids. The most common used organic phase change materials are paraffins. Melting temperature of paraffins concludes between 6°C and 108°C. Paraffins have linear alkane molecular chains with the formula of C_nH_{2n+2} with the chemical structure shown in Figure 2.21. Classification of the paraffins according to physical states and the number of carbon atoms done by Gulfam R. et al. where pure alkanes for 1–4 numbers of carbons in a gas phase at room temperature, liquid paraffins for 5–17 carbons, solid waxes for more than 17 are designated. Solid paraffin waxes are consisting a mixture of saturated hydrocarbons of high branched, linear, cyclo and isoalkanes. (Gulfam et al. 2019)

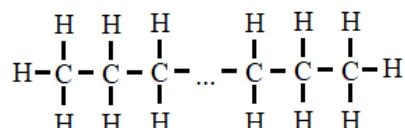

Figure 2.21. Paraffin- chemical structure (Boese et al.1999)

Packaging of n-alkanes demonstrates the crystal structure of paraffins in Figure 2.21 based on Boese and friends investigations. The investigation resulted that the molecular structures of the n-alkanes have a carbon skeleton with planar arrangement. The mean C(H₂)- C(H₂) and C(H₃)- C(H₂) distances of the investigated n-alkanes are both 1.521(1) Armstrong. The mean angles for C(H₂)-C(H₂)-C(H₂) and C(H₃)-C(H₂)-C are 112.8(1) and 113.5(1), respectively.

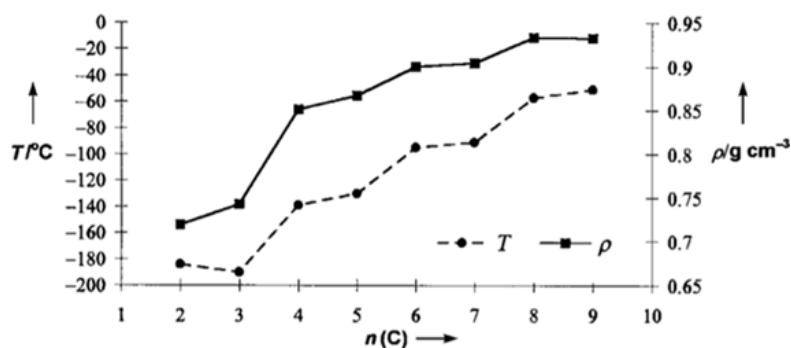

Figure 2.22. Trends in melting points [$T/^\circ\text{C}$] and densities [$\rho/\text{g cm}^{-3}$] of the n-alkanes C atoms [$n(\text{C})$] number increase (Boese et al.1999)

These values represent the X-ray standard values of undistorted n-alkanes. n-Alkanes with even-numbered carbon atoms have ideal intermolecular contacts at both molecular chain ends. n-Alkanes with odd-numbered carbon atoms have ideal intermolecular contact at one molecular chain end, and at other end have longer distance. This leads to less dense packing of individual n-alkanes obtained at odd-numbered n-alkanes because of this phenomenon which leads to lower melting points than even-numbered n-alkanes, as shown in Figure 2.23. Relation between the melting points and carbon atom number is shown at Figure 2.22. (Boese et al.1999)

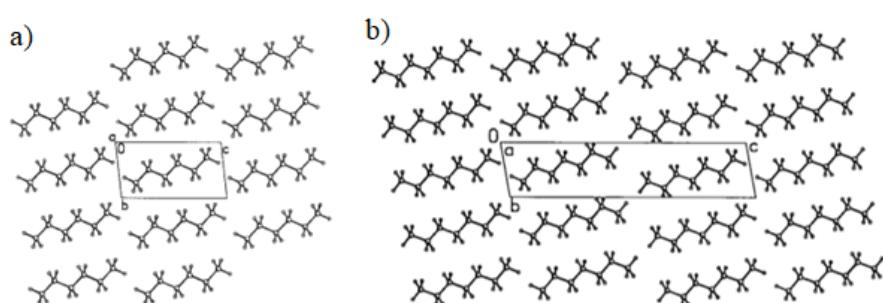

Figure 2.23. Packing of n-hexane (a) and of n-heptane (b) viwed along the a axis. (Mann et al. 2018)

Table 2.2 demonstrates the paraffins with different carbon atom numbers as a member of n-alkanes. Paraffins have low density, high phase change enthalpy with very stable melting and solidifying behavior. Boese's investigation declared that paraffins are very deaf to temperature changes with a thermal conductivity as low as 0,186 W/mK in solid state and 0,138 W/mK in liquid state as seen at Figure 2.24. Volumetric expansion of paraffin waxes from solid to liquid phase is as high as up to 15%. (Mann et al. 2018) This high volumetric expansion rate makes the paraffin ideal for paraffin actuators applications.

Paraffins are not soluble in water, do not react with common chemicals reagents. They are very compatible with metals. Paraffins have very few safety constraints. (Mehling and Cabeza, 2008) These properties provided to paraffin a wide application area in automotive engine cooling systems as paraffin actuators in thermostats with a very safe and high reliable lifetime experiences.

Table 2.2. Thermophysical properties of n-paraffins and commercial paraffinic phase change materials (Sharma and Tyagi 2009), (Khan et al. 2016)

Materials	Melting point (°C)	Latent heat (kJ/kg)	*Density (kg/m³)	**Thermal conductivity(W/mK)
n-Tetradecane	6	228-230	763	0.14
n-Pentadecane	10	205	770	0.2

*At 20°C., **Just above melting point (liquid phase).

-Main physical criteria of phase change materials in use of paraffin actuators are the phase change temperature to assure the initial movement temperature of the paraffin actuator. This specific temperature is called as first opening temperature of the paraffin actuator and must have an accurate value with a very narrow tolerance such as ± 0.5 °C. Because of that in terms of paraffins, a highly purified paraffin molecules are required to provide the accurate phase change temperature. This significant issue will be discussed in next topic.

-High thermal conductivity is required for the high sensibility to environmental temperature change. Low thermal conductivity causes postponed reaction of paraffin actuator to the temperature fluctuation of cooling circuits especially in terms of short time acceleration of engines. Thermal conductivity of paraffins will be interpreted under the topic thermal behavior of paraffins.

-Low thermal hysteresis is preferred to assure the equivalent / balanced actuator movement from solid to liquid and liquid to solid phase change determined as opening and closing of the actuator. Thermal hysteresis will be explained deeply under the topic thermal behavior of paraffins.

-Low subcooling is requested to maintain the same temperature for melting and solidifying of the paraffin compound. Subcooling of the phase change materials will be discussed under the topic thermal behavior of paraffins.

Following points can be concluded as the further selection requirements of phase change materials.

-High phase change volume expansion is required to achieve enough actuator stroke. For conventional applications an actuator stroke of 10mm is essential for fulfill the opening requirement of cooling circuits.

-High reproducibility of phase change is recommended for the actuation accuracy of whole lifetime. To validate the reproducibility up 100.000 cycles of cold/hot conditions is settled for modern engines.

-High environmental stability is required against high temperature, high pressure, chemical and physical factors. High temperature of engine environment up to 150°C, aggressive coolants and high inner pressure of paraffin actuators up to 200bars must be compensated by the paraffin compound. Non-toxicity is required for employee safety requirements and environmental reasons. Payable price for required for economical serial production cost required. A balance with high quality paraffin with price-performance ratio

2.2.3. Thermal behavior of paraffins

2.2.3.1. Thermal conductivity of paraffins

Thermal conductivity of paraffin is so low that in many application it is used as thermal insulation material. (Torres-Rodriguez et al. 2020) Table2.2 shows the thermal conductivity values of paraffins with different carbon atom numbers C₄₀ to C₅₀ which varies from 0.14 to 0.20 W/mK. A practical calculation of thermal conductivity of paraffins is established by Freund et al. which is meant to be valid for macrocrystalline paraffin waxes having melting points in the 50 to 54 °C range, over the temperature range from —180°C to +30 °C, using the following empirical -equation:

$$\lambda = 0.005 \cdot (1-0.0016t)$$

where λ is thermal conductivity in J/m•°C•s, and t is temperature in °C. The above relationship is acceptable as an approach for microcrystalline waxes and for paraffins liquid at ambient temperature. The relationship between thermal conductivity and temperature implies that increasing the temperature of the paraffin will decrease the thermal conductivity it. Investigations of Velez et al. confirm this relation with experimental results for n-pentadecane, n-nonadecane, n-octadecane, n-heptadecane, n-eicosane and n-hexadecane. Thermal conductivity reduction of paraffins occurs after phase change from solid to liquid significantly. Near the melting point of the paraffin there is a big jump of thermal conductivity is conducted which can be observed at all paraffins with different carbon atom numbers.

A more specific equation for the thermal conduction of phase change materials established by Bony and Citherlet where the thermal conductivity difference between the solid states and liquid states of a material, the model allows two different values for the conduction coefficient; one for the liquid phase and one for the solid phase. λ_{solid} refers to the thermal conductivity below the enthalpy value H1 at solid state before the phase change, and λ_{liquid} refers to the thermal conductivity above the enthalpy value H2 at liquid state after the phase change. $\lambda_{sol/liq}$ refers to the thermal conductivity between these two enthalpy values calculated by the following linear interpolation where, H^t is the value of enthalpy at temperature step t shown by Figure 2.24 depends on their study. (Bony and Citherlet, 2007)

$$\lambda_{sol/liq} = \lambda_{sol} + \frac{(\lambda_{sol} - \lambda_{liq})}{H2 - H1} (H^t - H1)$$

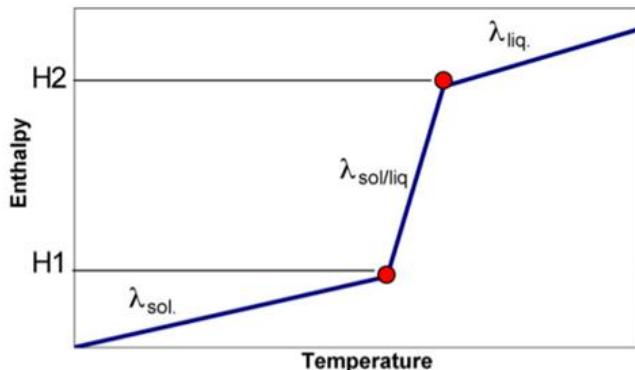

Figure 2.24. Thermal conductivity λ relative to enthalpy H . (Bony and Citherlet, 2007)

The temperature increase in solid state and liquid state has a smooth tangential line. At the temperature interval where the paraffin phase changed there is a steep tangential line in a very short period caused by the jump. This characteristic is repetitive revealed for investigated paraffin , n-eicosane, n-nonadecane, n-octadecane, n-heptadecane, n-hexadecane, n-pentadecane in different researchs studied by Velez, Holmen, Assael, Yaws, Wada, Bogatov, Rastorguev, Duan, Stryker, Nabil and Fang as seen in Figure 2.25. Figures are reproduced from works of Velez et al. 2015-I and 2015-II.

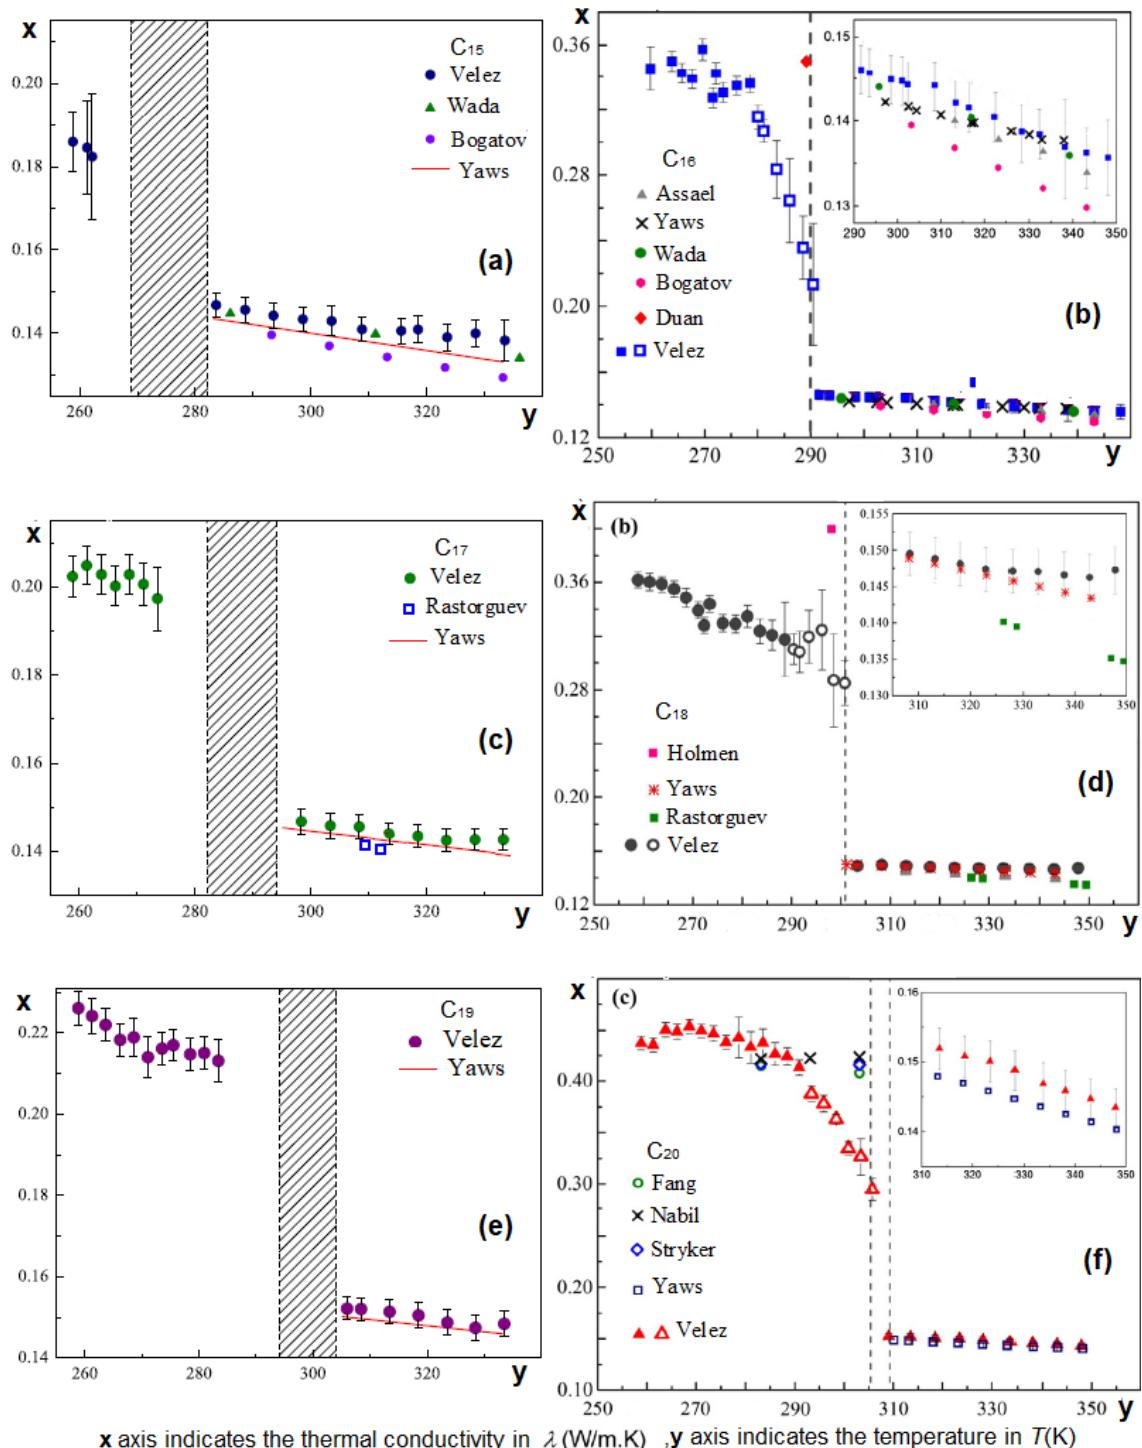

Figure 2.25. Thermal Conductivity measured for (a) C_{15} n-pentane, (b) C_{16} n-hexadecane , (c) C_{17} n-heptadecane, (d) C_{18} n-octadecane, (e) C_{19} n-nonadecane, (f) C_{20} n-eicosane in accordance with temperature, together with literature data as depicted. The patterned area correspond to the disordered solid state (between the two observed DSC peaks) (modified from source: Velez et al. 2015-I and 2015-II)

Another output of these investigations can be declared that the increase in carbon atom numbers of paraffin increases the thermal conductivity value respectively. Thermal Conductivity of odd-numbered paraffins presents a discontinuity at the solid-liquid phase transition. Thermal conductivity affects the response time of the paraffin actuators in terms of acceleration of the opening and closing stroke. Higher thermal conductivity of paraffin compound provides a faster volume expansion and it is converted to faster stroke of paraffin actuator. So that the higher sensitivity of paraffin actuator to environment temperature change can be granted.

2.2.3.2. Thermal hysteresis behavior of paraffins

Paraffin has a high thermal hysteresis value due to the thermal conductivity difference that of solid state and liquid state as well as during phase transition. Figures 2.25 shows the temperature dependend thermal conductivity measurements for given paraffin types. Hysteresis can be detected also in the enthalpy temperature curve with interruption of melting and cooling down of paraffin shown in Figure 2.26. (Andrassy, Z. and Szantho, Z., 2019) Thermal hysteresis of the paraffin can be observed at paraffin actuators in the curves of opening/closing stroke versus temperature while heating and cooling cycles. The closing curve does not match with the opening curve where always a temperate gap in-between exists.

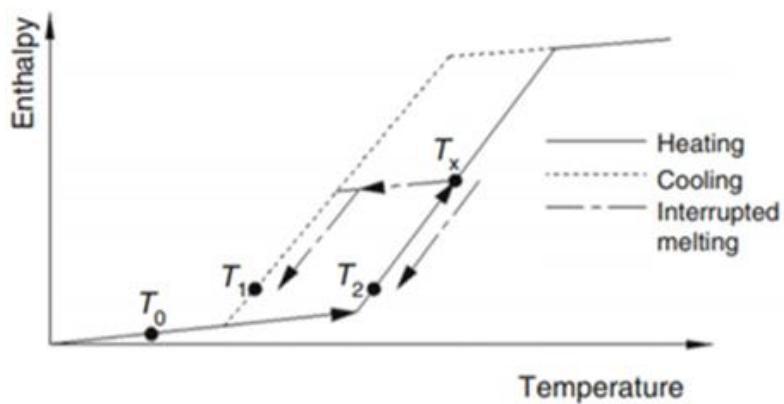

Figure 2.26. Phase change material behavior model while interrupted melting and cooling down of phase change material (Andrassy and Szantho, 2019)

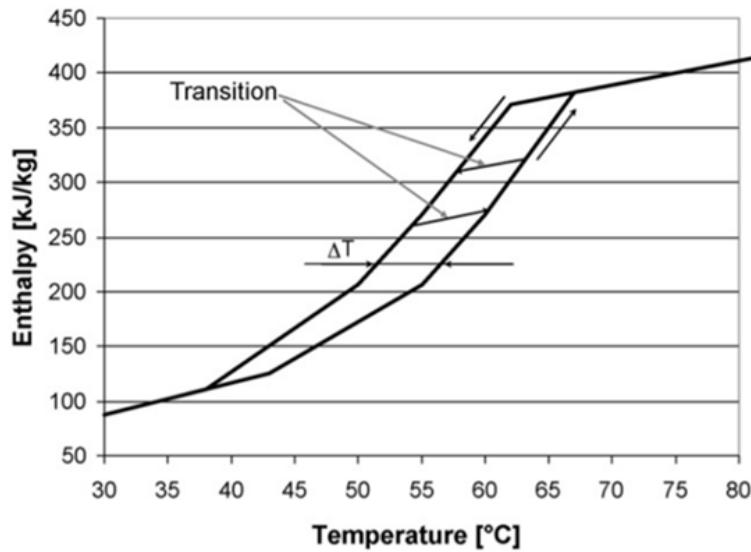

Figure 2.27. Hysteresis model (Chandrasekharan et al. 2013)

Thermal hysteresis behavior of phase change materials is modelled by Bony and Citherlet as Transition Model and by Chandrasekharan as Non-Transition Model in two different methods.

Transition model demonstrates the enthalpy curve shift in accordance with a differential temperature defined by a parameter. While a cooling or heating step in the phase change region, the slope of transition is equal to the solid phase one in the phase change bottom part. It is also same to the slope of the liquid phase in the phase change superior part. Enthalpy curve's discontinuity is avoided when the point of transition is close to the complete solid or liquid phase change as shown in Figure 2.28. (Bony and Citherlet, 2006)

At the transition model the phase change material shows hysteresis which initially is cooling in the phase change region, on the freezing curve where the transition specific heat is calculated as the average value of liquid and solid specific heats. Research of Chandrasekharan indicates the phase change materials which follow the same curve during melting and solidification in the same phase change region as shown in Figure 2.27. This non-transition approach covers the materials when it cools from a complete

liquid state. (Chandrasekharan et al. 2013) Thermal Hysteresis behavior of Paraffin actuator coincides with the non-transition model of Chandrasekharan.

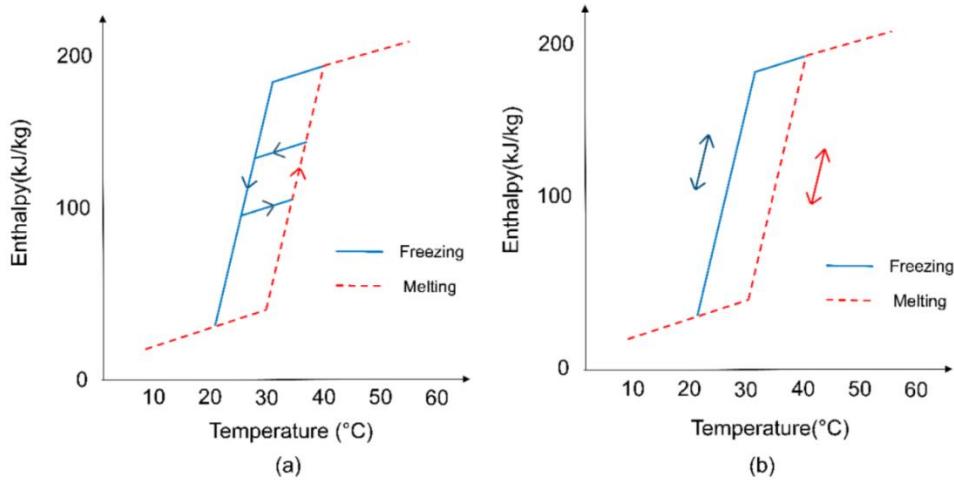

Figure 2.28 (a) Transition model (b) One curve model (Bony and Citherlet, 2006)

2.2.3.3. Subcooling behavior of paraffins

Subcooling of paraffin is a thermal phase change property which can negatively affect on closing function of paraffin actuator. If the liquid paraffin cooled down below melting temperature, the solidification is expected. If the solidification needs lower temperature than melting point, then this phase change phenomenon is called subcooling and this lower solidification temperature is called nucleation temperature. Sub-cooling's reason is, either growth rate of the nuclei or the nucleation rate (or both) is slow (Dincer and Rosen, 2002).

Subcooling effect of phase change materials can be seen at Figure 2.29 and a combination of subcooling and hysteresis at Figure 2.30 . (Bony and Citherlet, 2007)

At the temperature depended closing curve of the paraffin actuator can suffer from subcooling as shown in Figure 2.30.

Huang and friends investigated the subcooling of paraffins experimentally as paraffin-water emulsion. Pure paraffins showed small subcooling lower than 2K. Even though paraffins are having identical properties, the nucleation temperatures in the emulsion is

effected by paraffin type. Surfactants had insignificant impact on the melting temperatures of paraffins but surfactant type changes the subcooling and nucleation temperature. Nucleating agents can reduce the subcooling where the agent and fraction of agent had significant role both on the nucleation and melting temperature. Emulsions melting temperature decreases and temperature of nucleation increases with the increase of nucleation agent fraction. If the sufficient additional seeds in the droplets of paraffins procured by nucleation agent support, the subcooling can be reduced.

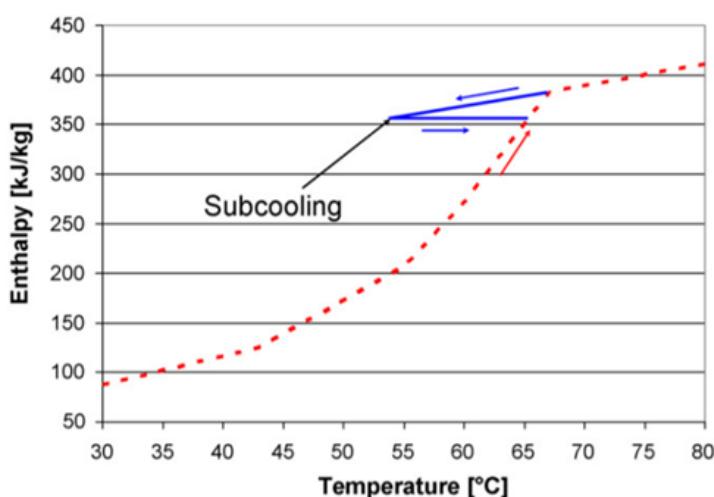

Figure 2.29. Subcooling model (Bony and Citherlet, 2007)

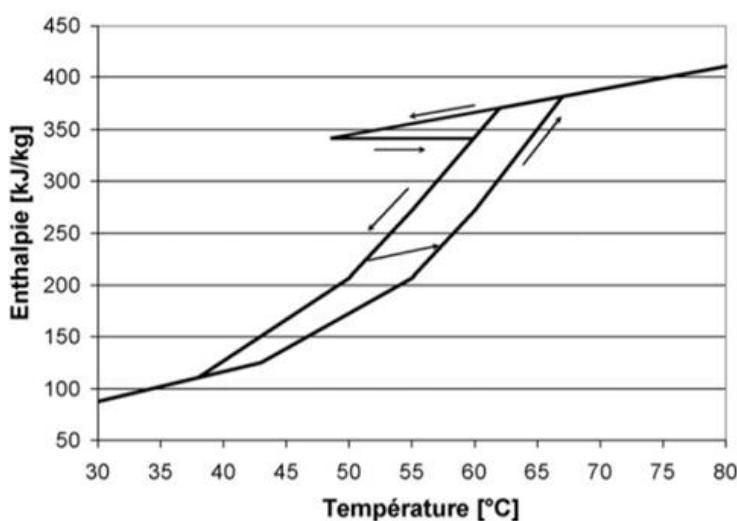

Figure 2.30. Combination of subcooling and hysteresis (Bony and Citherlet, 2007)

2.2.4. Thermal property enhancement of paraffins

Paraffins are widely used as thermal regulating materials because of its exclusive properties including diverse melting temperatures, chemically inert and stable behaviors. With outstanding heat capacity and thermal expansion properties paraffins have a large range of application area. However, it suffers from insufficient thermal behavior literally very low thermal conductivity. On the other hand, in accordance with its poor thermal conductivity, many research works have focused on enhancing the thermal conductivity of paraffin by combining it with other materials . (Kutlu et al. 2021), (Chaichan et al.,2015) , (Lin and Rao,2017), (Rathod and Banerjee, 2013)

Many different methods and materials are investigated to improve the thermal conductivity of paraffins. Enhancement methods can be classified according to medium type as using metallic and non-metallic medium, according to medium size and structures as using porous medium, meso to micro particles, nanoparticles and nanofibers.

Paraffins are thermally enhanced in following researches with metallic fillers and fins. An experimental setup was developed by Hussein et al. to investigate the influence of metallic strips and finned pipes on the enhancement of thermal conductivity of paraffin. The setup is functioning as heat transfer channels across the paraffin, where even paraffin turns to solid phase over pipes of heat exchange, heat transfer proceeds. Temperature homogeneity in the molten paraffin is improved by fins and metallic strips. Increase of thermal energy release from the paraffin to the streaming water has measured 47% by finned pipes application, and 304% by copper strips application. Placing copper strips in solar water heaters using paraffin for heat storage substance functioning as a heat transfer network made of channels, thereby improving the heating capacity of the heater and the heat transfer rate across the paraffin. Thermal transfer mode has changed from natural convection to conduction by addition of copper strips at finned and unfinned pipes application , where thermal transfer from the paraffin to the colder water pipes strongly supported. It is concluded that the possibilities of using metallic strips with

paraffins is higher than that of thermal fins depending on of its exclusive thermal transfer performance and its lower cost. (Hussein et al., 2017)

Li et al. investigated on open-cell metallic foam filled paraffin in terms of melting phase change heat transfer theoretically and experimentally. Seven foam samples with high porosity made of copper , and phase change material of paraffin used in the experiments. Distribution of temperature inside media is investigated where the effects of parameters like morphology, porosity, pore diameter studied. A heat transfer enhancement is revealed during melting. Thermal non-equilibrium, non-Darcy effect, and local natural convection is measured, and resulted in conformance with experimental results. The overall thermal resistance of the paraffin-foam composite was lower than that of pure paraffin. Porosity has influenced more than pore density to thermal conductivity. Decreasing pore density and decreasing porosity is required to improve the uniformity of thermal distribution. (Li et al. 2012)

Chaichan presented his attempt on enhancing thermal conductivity of paraffin by the addition of Al_2O_3 , TiO_2 and carbon nano tubes to make a phase change composite material of enhanced thermal conductivity and high latent heat. The nanocomposite materials showed improved properties than pure paraffin. Increase of thermal conductivity achieved by increasing mass fraction of nano-particle in the paraffin. With addition of 5% TiO_2 and Al_2O_3 , the enhancement of thermal conductivity was 40%, and 60% respectively. Charging period is decreased by nano-particle addition into paraffin at melting temperature. (Chaichan et al.,2015)

Khedkara et al. studied in effects of Fe_3O_4 nanoparticles addition into paraffin on the viscosity and thermal conductivity. % 0.01 to % 0.1 range of volume fraction of nanoparticles were investigated. Ultrasonic device is used for the intensive dispersion of Fe_3O_4 nanoparticles into paraffin. The Fe_3O_4 nanoparticles with 25 nm avarage diameter used. TA instruments rheometer is used for viscosity measurement and KD2Pro device based on transient hot-wire used for measurement of thermal conductivity. Increase of thermal conductivity is achieved by increase in volume fraction of particle. 20% enhancement is recorded with 0.1 volume fraction of Fe_3O_4

nanoparticle addition in paraffin at room temperature. The effects of shear rate and concentration and on the rheological properties and the thermal conductivity of nanofluids were studied. The nanofluid composition showed improvement in both viscosity and thermal conductivity, and the percent increase in thermal conductivity was much higher in comparison with viscosity . The paraffin - Fe_3O_4 nanofluid represented Newtonian property at high shear rates and non-Newtonian property in the low shear rate range. (Khedkara et al., 2013)

Another study on thermal property enhancement with metal oxide nanoparticles is made for paraffin as phase change material by Al_2O_3 nanoparticles emulsifying in paraffin by using non-ionic type surfactant. 5 and 10 wt.% alumina nanopartical addition investigated experimentally. Dynamic viscosity and thermal conductivity for the paraffin-nanoparticle emulsion showed a nonlinear increase in comparison with pure paraffin depending on temperature. Thermal conductivity of the paraffin-nanoparticle emulsion results compared by various temperatures together with that of the pure paraffin. Thermal conductivity of the paraffin-nanoparticle emulsion was increased in accordance with mass fraction of the nanoparticles more than 6% and 2% respectively, for the paraffin emulsion with 10 wt.% and 5 wt.% of nanoparticles at 30 °C temperature. Thermal conductivity improvement relatively at 60 °C increased over 17% with nanoparticle addition of 10 wt%. (Ho and Gao, 2009)

Sahan and Paksoy synthesized ZnO nanopowder with hexagonal crystal structure with nano-tubular shape for the thermal property improvement of paraffin. In terms of thermal energy storage application, a paraffin- ZnO composite was prepared with 10% wt. Experimental investigations resulted with reduction of heat storage capacity where phase change property was stable. (Sahan and Paksoy, 2017)

In a comparative research the usage of phase change material and nanofluid for photovoltaic fluid collector system as coolant where ZnO and CuO nanoparticles addition is investigated experimentally. Thermal efficiency, energy, surface temperature and the comparison between two nanoparticle type is studied. In comparison with classicla method, the CuO nanoparticle implemented version achieved 15% higher

image of electric. The CuO nanoparticles addition increased the thermal image up to 8% for photovoltaic thermal and 12% for paraffin material without any consumption of energy. The electrical efficiency of the paraffin /CuO showed more intense effect than paraffin /ZnO by resulting 16% more efficiency. Surface temperature reduction to considerable level achieved by nanoparticle addition, besides enhancement of the power efficiency. The overall thermal output of paraffin was raised by 46% in comparison with the photo voltaic system. It is concluded that of the photovoltaic thermal system's specific heat can be increased and the thermal losses can be reduced momentarily by paraffin medium usage. It was revealed that paraffin –nanofluid medium is an suitable choice for enhancement of cooling performance in photovoltaic thermal systems without additional energy consuming supplementation . (Manigandan and Kumar, 2019)

Wang et al. investigated on CuO-paraffin nanocomposites regarding thermal conductivity enhancement and dispersion stability. CuO nanoparticles added to paraffin with mass fractions of 0.3, 0.6, 0.9 and 1.2%. Morphology of nanoparticle and stability of dispersion in CuO-paraffin nanocomposite phase change media were investigated by scanning electron microscopy and spectrophotometer . Results declared that increase in the thermal conductivity of the nanocomposite is measured by 24.4% in case of 1.2% CuO nanoparticles addition into the paraffin, as well as reduction in the phase change latent heat measured as 1.5%. (Wang et al. 2020)

Another investigation on thermal conductivity enhancement of the paraffin wax by copper oxide nanoparticles addition issued by Kumar et al. Samples of paraffin nanocomposite were synthesized by dispersing 2.0, 1.5, 1.0, 0.5, and 0 wt. % of CuO nanoparticles in paraffin wax. The CuO nanoparticles raised the paraffin's thermal conductivity in solid and liquid phase to 172.7%, 131.8, 95.5%, 50% and 8.89%, 7.785%, 6.11% and % 2.77% and respectively. Field emission scanning electron microscope is used for the observation of the surface morphology of the CuO nanoparticles-paraffin mixture of in the composite structure. Increase in CuO nanoparticles proportion in paraffin wax enhanced the thermal conductivity substantially. The experimental values are looking higher than the theoretical models;

still variation in thermal conductivity follows the same trend as by the theoretical model. Solid phase of paraffin was raised drastically, in comparison with liquid phase thermal conductivity. (Kumar et al. 2020)

A comparable research with ours is investigated by Owalabi et al.. Paraffin nanocomposites prepared with addition of Al, Cu, Fe and Zn nanoparticles into pure paraffin wax with weight ratio of 1.5, 1.0, and 0.5% to investigate the thermal energy storage behavior theoretically and experimentally. Thermal behavior of the nanocomposites were enhanced by increasing the weight ratio of nanoadditives regarding thermal energy storage properties. Zn and Cu nanoparticle addition of 1.5 wt.% improved the nanocomposite thermal conductivity by 61.5 and 20.6% respectively. A Reduction of specific heat is revealed where a proportional increase of thermal conductivity and thermal diffusivity observed. The Hamilton-Crosser and Maxwell models expressed the nearest results to the experimental values. The improved paraffin nanocomposites showed better capability of thermal energy storage, especially for applications of solar thermal energy storage. Overall results of the research predicted that the thermal conductivity of the nanocomposite is enhanced in terms of 1.5 wt.% addition of Zn, Fe, Al and Cu nanoparticle addition, by 61.5, 52, 24.2, 20.6 %, respectively. (Owalabi et al., 2016)

Amin et al. reserached the effect of nanoparticle addition into paraffin to observe the change in the nanocomposite's latent heat. Paraffin was used as phase change material with ZnO , TiO_2 , CuO and Fe_3O_4 nanoparticles are added. Paraffin and nanoparticle mixture prepared by sonification with the weight ratio of of 15, 10, and 5 wt%. Paraffin's melting point, thermal properties and latent heat were examined with Differential Scanning Calorimetry . Test results revealed that the paraffin nanocomposite's latent heat was increased by 20.17%, 7.5%, 78.89% and 20.67% for the addition of ZnO (5 wt%), TiO_2 (15 wt%), CuO (10 wt%), and Fe_3O_4 (5 wt%), respectively. 10 wt% mass fraction of CuO nanoparticle-paraffin showed better result in terms of latent energy storage. On the other hand nanoparticles addition did not affected on the paraffins melting point distinctly. According to the investigation it can be revealed that paraffin –metaloxide nanoparticle nanocomposite is an based nano-phase

change material is a superior media in therms storage of thermal energy. (Amin et al., 2017)

2.2.5. Dispersion thermal stability of paraffin nanocomposites

The thermal analysis, rheology and dispersion behavior of nanomaterials in paraffin was experimentally evaluated in terms of ZnO nanoparticles by Suhaib et al. The ZnO nanoparticles are dispersed in liquid paraffin at different concentrations (0–1 wt%). Sedimentation and Dynamic Light Scattering (DLS) methods are used to determine the dispersion stability. The thermal conductivity of the stabilized nanofluid at concentrations and different temperatures are investigated and an enhancement till 18% is revealed for 0.5 wt% of ZnO paraffin nanofluid. (Ilyas et al., 2019)

Conductive nanoparticles implemented nanocomposites were aimed to be added into paraffin of phase change material for improvement of thermal transfer where the dispersion stability has an important effect on the long term thermal transfer behavior of the specific application. Although many researches involved on the thermal property improvement of paraffin with nanoparticle addition, there are not sufficient investigations on the long term effect on thermal behavior. Study of Saydam and Duan attempted to understand the precipitation behavior by researching the stability of nanoparticle enhanced nanocomposite under repeated thermal (solidification- melting) cycles. Base phase change paraffin is used for the mixture with nanoadditives of multi-walled carbon nanotubes, graphene nanoplatelets and Al_2O_3 . Stability of various nanocomposite preparations was experimented applying continual thermal cycles implemented in a special thermal chamber. After a few thermal cycles, deposition/coagulation of nanoparticles were registered irrespective dispersion process of the nanoparticle type and concentration. The highest thermal conductivity improvement was registered for 2%wt paraffin-multiwall carbon nanotubes wax by 13% at the temperature of 35 °C. A limited thermal conductivity improvement is also registered by nanoparticle addition of Al_2O_3 . Nanoparticle precipitation is observed after common time for thermal equilibrium occured. Compared with pure paraffin, nanoparticle-paraffin nanocomposites showed negligible imrovement in terms of thermal transfer due

to the sedimentation and nanoparticle agglomeration, therefore it was not providing the required nanoparticle network within the measurement region. (Saydam and Duan, 2019)

2.2.6. Nanofiber - paraffin interaction

Leakage of paraffin causes a limited use for thermal applications such as heat storage, thermal regulating, and phase change material. In order to use paraffin with considering leakage, paraffins have been encapsulated into other materials for stable usage. Encapsulation of paraffin in cellulose nanofibers and the formation of stable thermal regulation nanocomposites were investigated by Li et al.. Paraffin was encapsulated by cellulose nanofiber through a pickering emulsion method, while simultaneously forming of composite material. The phase change material (PCM) composite showed a solid content of paraffin of more than 72 wt.%. (Li et al., 2017)

Iqbal and Sun reported development of microencapsulated paraffin - monofilament fibre using melt spinning method. Incorporation of 12% microcapsules was successfully implemented into the monofilaments of polypropylene with the latent heat of 9.2 J/g. Mechanical properties and surface morphology of monofilament of the produced fibre is also studied. The developed statistical model for modulus of monofilament fibre, tenacity and latent heat was complying with the fibre properties of ampirical results. The investigation achived to build thermoregulating structure of paraffin microencapsulation with melt spun monofilament fiber.

Lu et al. used coaxial electrospinning method for a simple production process of paraffin loaded flexible nanofibers with structure of core-sheath. Polymethyl methacrylate sheath-layer encapsulated the paraffin core layer successfully. An increase in speed rate of core solution from 0.1 mL/h to 0.5 raised the fiber core diameter from 395 nm to 848 nm. 58.25 J/g of latent heat and -56.49 J/g solidifying enthalpy are registered by the core-sheath nanofiber films. On the other hand a limited change in latent heat was revealed after 200 thermal cycles, which shows that it is useful for the

paraffin-loaded core-sheath structure to improve the thermal stability properties and defeat the leakage issue the thermal regulation application.

Another investigation applied coaxial electrospinning method using ethanol as solvent for the production of nanofibers with paraffin as core and hydrophobic shell by Sun et al.. Effects of Core and shell fluid's flow rate and ethanol - polyvinyl butyral concentration on the polyvinyl butyral-paraffin nanofibers morphology were studied. The thermo-regulating capability was demonstrated by observing the Inner and surface temperatures of fiber covered model houses was observed to determine the ability of thermal regulation. Increase in shell flow rate and concentration of polyvinyl butyral improved the core-shell polyvinyl butyral-paraffin nanofibers morphology which enables enhanced encapsulation. Higher core flow rate with constant shell flow rate resulted better encapsulation of paraffin in polyvinyl butyral nanofibers. Production parameters of 0.60 ml/ h core flow rate and 3.0 ml/h shell flow rate with 20 % (w/v) concentration of polyvinyl butyral reached to the up to 46.4 % encapsulation ratio of the polyvinyl butyral-paraffin nanofibers. The enthalpy of crystallization and enthalpy of melting of these polyvinyl butyral-paraffin nanofibers were 106.5 J/g and 105.9 J/g , respectively. The paraffin-polyvinyl butyral nanostructure shows a good thermal regulation property in solar irradiation, optimizing the temperature of 28°C. The fabricated paraffin-polyvinyl butyral nanofibers resulted successful repeatability and stability in the thermal regulation capability.

Mengjin et al. studied on thermally regulating fibers focused on paraffin and polyvinyl alcohol which was produced via wet-composites spinning. In the produced fiber, paraffin was supporting phase change material for energy storage and polyvinyl alcohol was matrix polymer. Fiber's thermal properties, thermal stabilities, mechanical properties, fiber morphology and the thermal properties of the fibers were investigated. The results revealed that the thermoregulatory fiber has satisfying stability 30 % or less paraffin content. The best fiber properties of strength was 2.6 cN/dtex, elongation at break was 19.9%. (Mengjin et al., 2008)

2.2.7. Separation and Purification of Paraffins

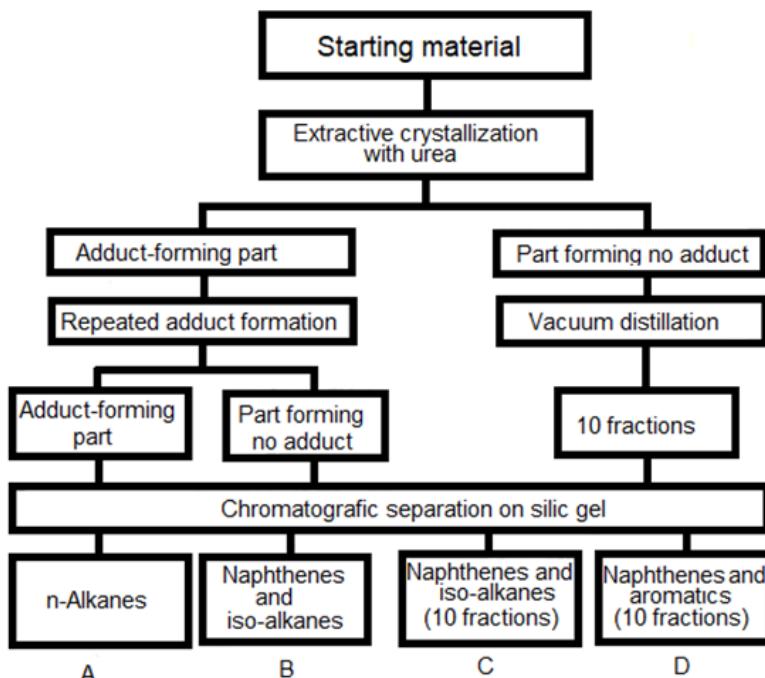

Figure 2.31. Diagram of separation of slack wax. (Freund et al., 1982)

Separation of the paraffin wax from other n-alkanes and purification according to melting point is processed by petroleum industrial technologies. Slab wax is paraffin wax produced by cooling, pressing and sweating from low-viscosity distillates. Slack wax is intermediate product of cooling and pressing without sweating or refining. Scale wax is the product obtained by just sweating. Products obtained from slack waxes subjected to further purification are recognized by the attribute “purified”. Diagram of separation of slack wax show the steps for the separation of slack wax. The result of this separation steps for the group B is presented in Figure 2.31 where the hydrocarbon composition and distribution by carbon number is declared, by Freund and friends. (Freund et al., 1982)

It is revealed from Figure 2.32 that after this classical separation method there are still diverse kind of paraffins in the composition and further separation / purification is necessary for an accurate melting point of the paraffin with less deviation. (Freund et al., 1982)

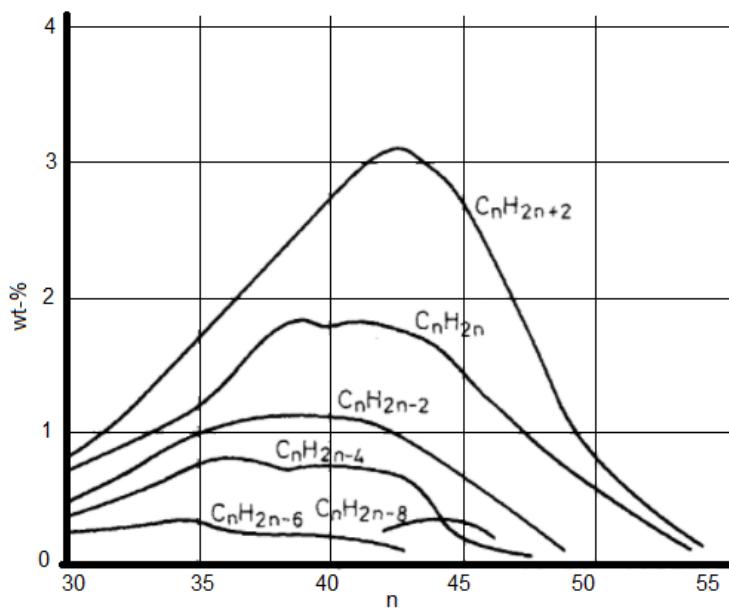

Figure 2.32. Hydrocarbon composition of fraction B obtained from slack wax from neutral oil (Freund et al., 1982)

Purification of the 29 types of Paraffin by distillation studied by Forziati et al. where refractive index measurement, purification results, density, boiling point and boiling point's pressure coefficient at 1 atm and, particularly point of freezing, including calculated impurity amount reported. Number of distilling columns and distillation time is recorded as process parameters.

Gang et al. studied on driving force vacuum sweating for forced paraffin separation process. The result showed that vacuum pressure for forced separation is applicable with an optimal pressure of 80 kPa. Also the final temperature affected on the product yield, where the driving force is raised by final temperature increase while sweating enhance the productivity and shortened the fabrication time. The analyse results of X-ray differaction, , gas chromatography, fourier transform infrared spectroscopy, differential scanning calorimetry revealed that distribution range of the carbon atom number in the products are narrowed due to increase in temperature of forced separation and n-paraffin content is drastically increased. (Gang et al. 2019)

Zolotarev and Nigmatullin developed a method where slack wax is processed with a aluminum chloride complex for enhancement of the purity by improving the efficiency of deoiling. Deoiling supported the slack wax purification, where the oil content is decreased by 15-20% relatively. (Zolotarev and Nigmatullin, 1997)

A filter medium with nanofiber coating is used for crude wax purification by Missau et al. The study focused on the elimination of inorganic contents in the crude wax composition. Forcespinning equipment is used for Nylon-6 nanofibers /nano structure surfaced filter media production. A comparison made between the filter media with nanofiber-coating and with the one without treatment in terms of filtering performance. The filter cake's specific resistance, resistance of filter medium and volume of the filtrate defined, keeping pressure, temperature, filtering time and constant at 2.5 bar, 170°C, 1h, respectively. The excellent filtering performance performed by the filter with nanofiber coating, better inorganic material retention and promoting greater wax filtrate volume and with values of 99,6% and $5,39 \times 10^{-5} \text{ m}^3$ and respectively. (Missau et al., 2018)

2.2.4. Polyacrylonitrile/ paraffin and phase change material investigations

Paraffin – polyacrylonitrile studies investigated mainly in terms of taking the advantage of phase change properties of paraffin and use it for thermal applications in nano and micro scales. More investigations worked on diversed non-paraffin phase change materials and polyacrylonitrile fibers.

Polyacrylonitrile together with the vinylidene chloride polymere and the paraffin n-octadecane investigated by Zhang and friends. Wet spinning process is used to produce 40 wt % paraffin containing fibers in microscales. The fiber morphology, structure and thermal properties were investigated by using scanning elec tron microscopy, fourier transform infrared , wide -angle X - ray diffraction, dynamic mechanical analysis and differential scanning calorimetry. Thermoregulation properties of heat evolving and heat absorbing temperatures of the fibers are increased by increasing of paraffin content. The crystallization enthalpy and melting enthalpy was increased by increasing the paraffin

content. On the other hand increasing the paraffin amount in fiber content, decreased the modulus of the fiber modulus. (Zhang et al., 2006)

Wan and friends investigated coaxial electro-spinning technology to produce a wearable phase change material - polyacrylonitrile core-sheath nanofiber. Polyacrylonitrile was considered as the sheath material to use the advantage of fibers as comfort for skin of human body, and paraffin and isopropyl palmitate for thermal management behaviour. The electrospinning parameters adjusted for encapsulating a phase change material by a polyacrylonitrile shell, resulting a uniform sheath–core structure. SEM images showed the successful formation of the hollow nanofibers and phase change material encapsulation with a narrow fiber diameter deviation of the nanofibers shown as in Figure 2.33. The study proved the fabricatin of Polyacrylonitrile/Paraffin sheath - core nano-fibers with uniform thermal behavior. (Wan et al., 2016)

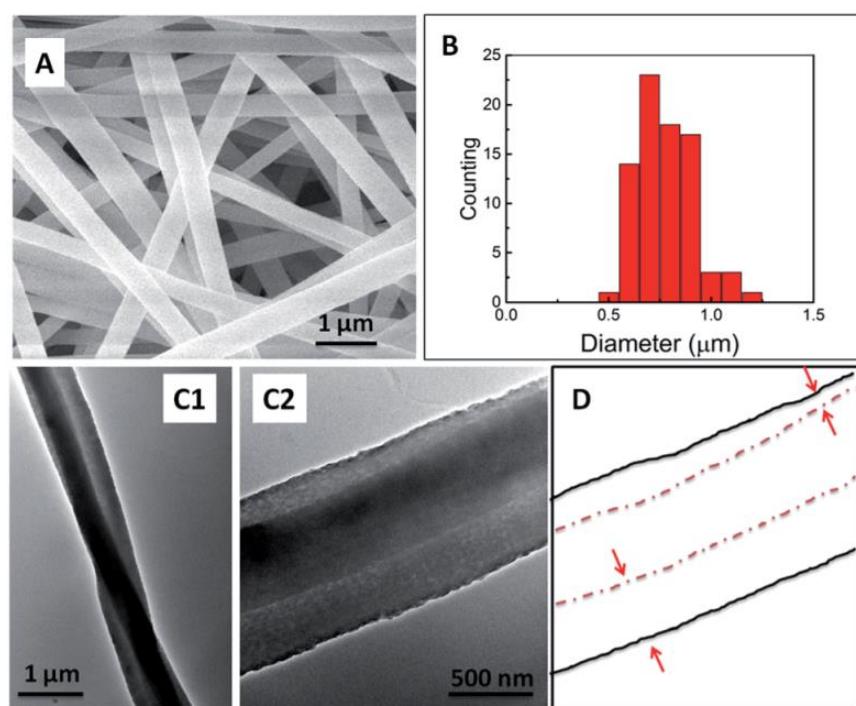

Figure 2.33. PAN/IPP fiber morphology with 2 mL /h PAN flow rate. (A) SEM nanofiber images, (B) distribution of fiber diameter, (C) HR-TEM nanofiber images, (D) sheath–core structure sketch. uniform sheath thickness depicted by arrows. (Wan et al., 2016)

Che and friends improved a simple centrifugal spinning method to replace electrospinning, using phase changing material polyethylene glycol and supporting polymer polyacrylonitrile with conducting nano-SiC filler. The phase change process did not affect on the fiber shapes. DSC results showed that 69.91 J/g latent heat of phase-change and 51.31 °C melting temperature achieved with 4.0 wt% nano-SiC containing nanofibers. A 79% improvement on fiber's thermal conductivity achived with SiC addition shoen in Figure 2.34. The thermal conductive enhancement was attributed to effective thermal transfer provided by nano-SiC. After 200 times thermal cycles, Phase change fibers latent heat values of the were still in acceptable range. On the other hand capacity of latent heat and fiber morphology affected negatively with the increase of nano-SiC in the fiber structure. Shape stability of the structure improved via nano-SiC incorporation in the phase change-nanofiber. (Che et al., 2020)

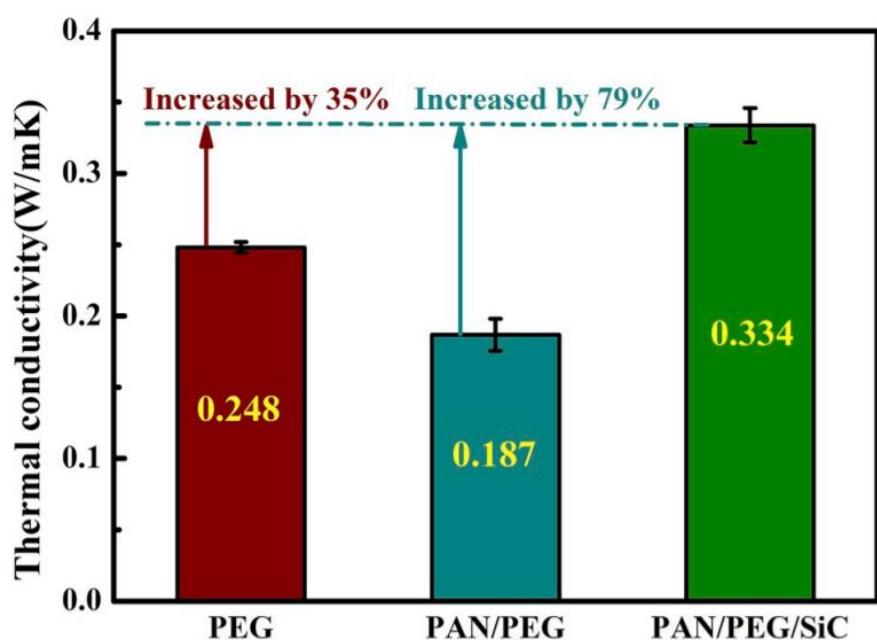

Figure 2.34. Thermal conductivity values at 25 °C, of PAN/ PEG/SiC, PAN/PEG, pure PEG phase change materials (Che et al., 2020)

Application of phase change materials in systems for latent heat storage is one of the most effective technology depending on conversion of energy with minimum loss. Single electrospinning process is used for composite phase change fiber fabrication made of polyacrylonitrile with the phase chage materials lauric acid and methyl

palmitate of fatty acid eutectics. Copper nanoparticles combined for enhancement of the phase change material. Fabricated composite fiber's structure and morphology observed by SEM. Moreover the thermal performance is also investigated. The three-dimensional fiber structure supported the liquid fatty in terms of stability. Thermal conductivity is enhanced more than 115.2% with nanoparticle addition where 85.07 J/g of latent heat measured. Thermal conductivity values listed in the Table 2.3. Thermal reliability of the fiber-phase change characteristic was tested with multiple thermal cycles. Thermal cycles with long-time periods did not affect on phase change properties and confirmed the excellent thermal reliability. (Xie et al., 2020)

Table 2.3. Methyl palmitate -Lauric acid/ PAN composite fibers and PAN fiber thermal conductivity values with/without Cu Nanoparticles addition (modified from source: Xie et al., 2020)

Samples	Methyl palmitate-Lauric acid/PAN (100/100) 1wt% Copper Nanoparticles	Methyl palmitate-Lauric acid/PAN	PAN	Methyl palmitate-Lauric acid/ PAN
Thermal Conductivity (w/m.K)	0.10557	0.11067	0.18252	0.23810

An innovative investigation made by Kea and Weia on to fabricate fiber membrane based phase change material with higher form stability. Three different phase change materials with melting temperature in the range of 20–33 °C capric-myristic acid binary eutectic , capric- palmitic-stearic acid ternary eutectic and butyl stearate are investigated for physical adsorption into the nanofibrous membranes. Polyacrylonitrile nanofibers filled with silver nanoparticles is produced with electrospinning as nanofibrous membranes. Thermogravimetric analysis, differential scanning calorimeter, scanning electron microscopy, measurement of solidification and melting times used for thermal properties characterization and fiber morphology detection. Below 100 °C operation

temperature, nanofibrous membranes made of polyacrylonitrile/sliver nanoparticles composite are showed good thermal stability. Uniformly dispersion of solid-liquid phase change materials in the nanofiber –membrane structure is showed Figure 2.35. Thermal conductivity values are improved distinctively according to results of thermal performance chracterization depending on excellent thermal conductive silver nanoparticle addition. (Ke and Wei, 2019)

(Ke and Wei, 2019)

3. MATERIALS and METHODS

3.1. Paraffin/PAN Hybrid Nanofibers for Paraffin Actuators

3.1.1. Chemicals and equipments

Polyacrylonitrile (PAN, Mw of 150.000) and N,N-dimethylformamide were supplied from Sigma Aldrich and used without any purification. The paraffins (P) were purchased from the International Group, Inc (Toronto, ON, Canada). New Era (NE-300) micropump was used as a solution feeding equipment. Gamma High Voltage Research D-ES 30PN/M692 power supply was employed as a voltage source for electrospinning process. Plastic medical syringe with needle gauge number 21 was used, and the needle of syringe was cut to set 1.5 cm before the usage.

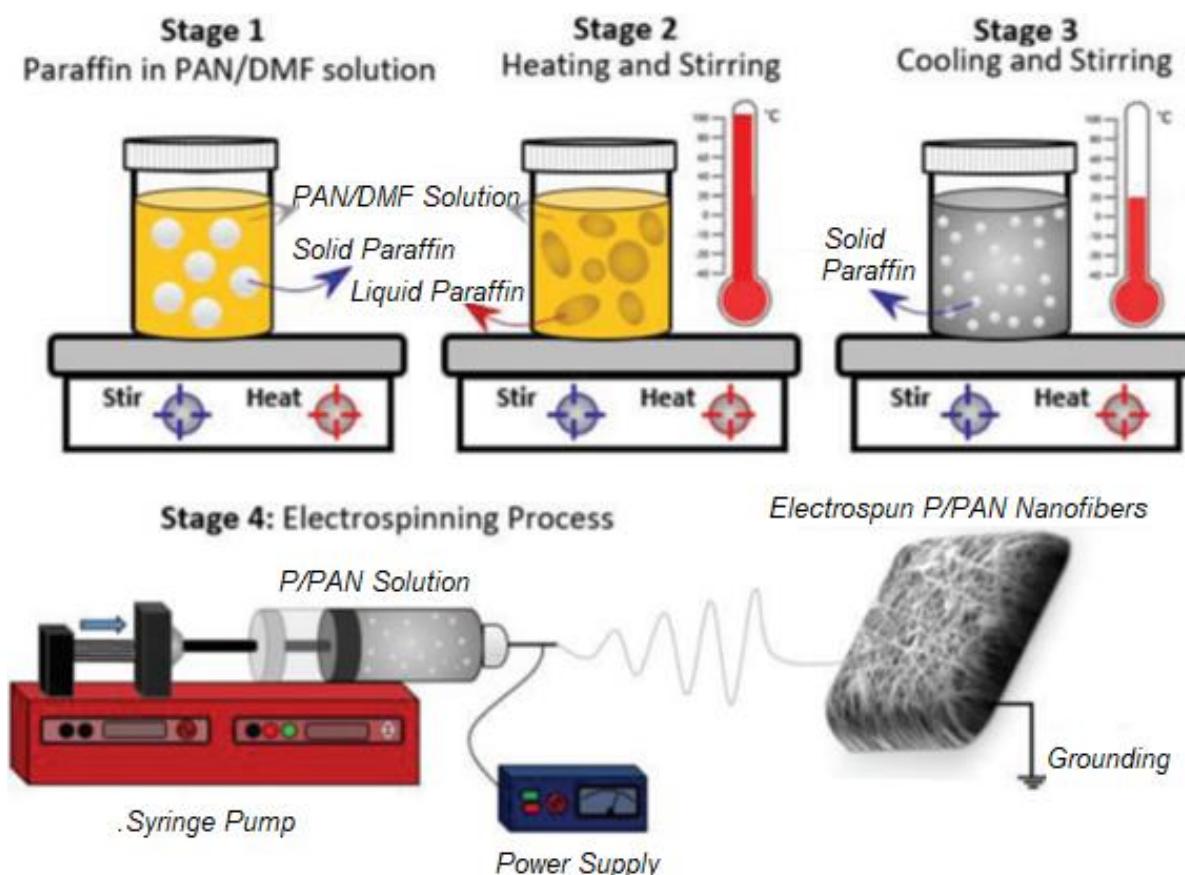

Figure 3.1. Schematic illustration of the one step preparation P/PAN solutions and nanofiber production via electrospinning process.

Stroke Curve and Hysteresis Measurement

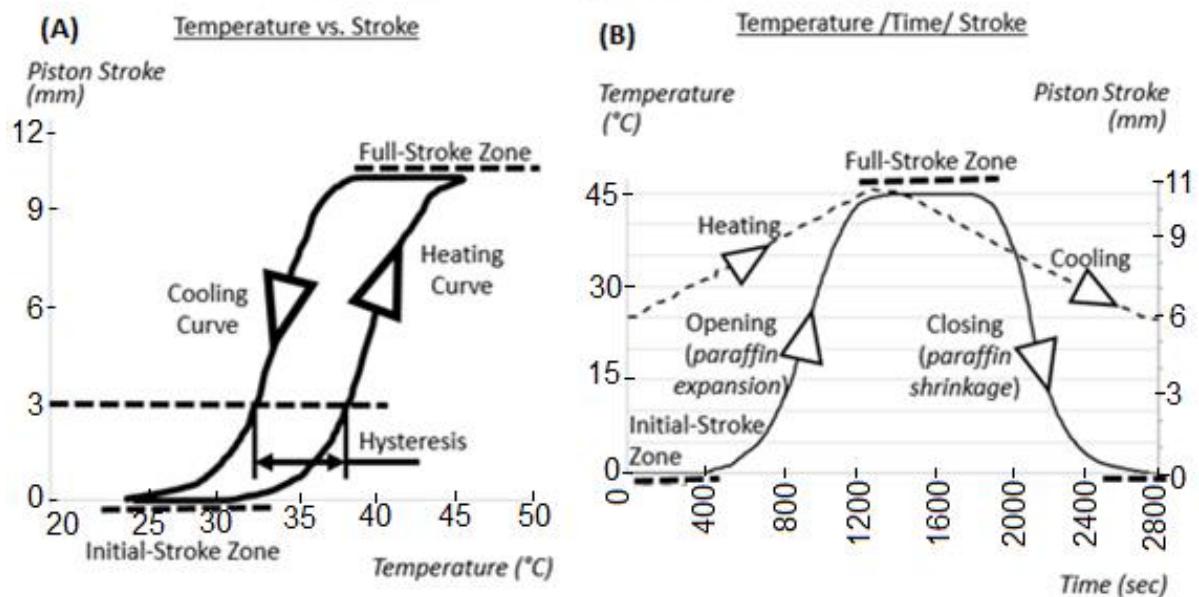

Figure 3.2. Steps of sample preparation from as spun nanofibers, testing and analysis

Table 3.1. Paraffin actuator samples: P/PAN hybrid nanofiber composition

Samples	N-Eicosane weight (mg)	P/PAN hybrid nanofiber weight (mg)	N-Eicosane rate by weight (%)	P/PAN hybrid nanofiber rate by weight (%)
S1	440	0	100	0
S2	429	11	97,5	2,5
S3	418	22	95	5
S4	407	37	92,5	7,50
S5	396	44	90	10

3.1.2. Preparation of solutions and electrospinning of P/PAN hybrid nanofibers

Firstly, 8 wt.% of PAN in DMF was dissolved by magnetic stirring at an ambient condition in a glass vial. Preparation of PAN nanofiber by using electrospinning method has been investigated by several groups (Gu et al., 2005), (Zhang et al., 2014). In this study, 6ml of the prepared solutions were filled into the separate vials. The defined weight of solid paraffins were added into each vial. Two different sample groups were prepared. In the first group, the same amount of paraffins was added into the same amount of PAN/DMF solutions, and weight of paraffin and PAN were the same in the final solution. The labels of the selected paraffin types were P1, P2, P3 and P4 for the samples which had melting points of 32, 58, 89 and 114°C. Paraffin/polyacrylonitrile hybrid nanofibers were labeled as P/PAN (Ex: if P3 was used in P/PAN nanofibers, it was labeled as P3/PAN). In the second group, P3 was selected and different amount of paraffins were added into the same amount of PAN/DMF solutions. P/PAN weight ratios were adjusted as 15/100, 30/100 and 100/100 in the PAN/DMF solutions, and the samples are symbolized as P3/PAN-1, P3/PAN-2 and P3/PAN-3. All the vials were capped strongly. Then the vials were put on a magnetic stirrer and stirred by simultaneous heating. Each stage of the solution preparation was schematically shown in Figure 3.1. When the paraffins in the solutions were transformed to liquid state (stage 2), the solution was stirred harshly (at 500 rpm) to break liquid paraffin apart into small particles and the heater was turned off and stirring was continued until the temperature of the solutions reached to the ambient condition. When the temperature came to the ambient condition, small paraffin particles were obtained in the solution (stage 3). The

prepared final solution was filled in the plastic syringes (21-gauge, needle length was 1, 5 cm) and electrospinning was performed and demonstrated as stage 4 in Figure 3.1. Electrospinning was carried out with 1ml/h feeding rate and 17.5 kV applied voltage, and keeping the collector to tip of the needle distance as 15 cm. In order to eliminate clogging of the needle and unwanted spraying of the solution, tip of the needle was cleaned up with 5 minutes intervals. The solution was ejected from the needle to the grounded collector, and finally P/PAN hybrid nanofibers were obtained on the collector in the mat form. DMF in the solution was evaporated during the nanofiber formation between tip of the needle and the collector.

Characterizations of P/PAN hybrid nanofiber Morphological investigation of as-spun pure PAN and paraffin loaded P/PAN hybrid nanofibers was conducted with a ZEISS EVO 40 scanning electron microscopy (SEM). The samples were conductive coated with gold-palladium (60/40) about 30 seconds for better imaging by using a Baltec sputter coater. Fiber diameter was measured by pixel processing based free, open source program, ImageJ program (The National Institutes of Health, USA). 100 nanofibers were measured in the SEM images. Fiber diameter distribution chart built as fiber diameter vs frequency in MS Excel. FTIR spectra was acquired with a FTIR spectrometer (Bruker Optics Tensor37, Ettlingen, Germany) equipped with ATR detector. The measurements were carried out between 4000 and 400 cm^{-1} wavelength with 4 cm^{-1} resolution.

DSC tests were carried out with Differential Scanning Calorimetry Analyzer (TA Instruments/Discovery DSC251, New Castle, USA) using 10C/min of heating rate from 0 to 400 °C. TGA tests were conducted with a simultaneous thermogravimetric analyzer (Hitachi Hi-Tech STA7200, Tokyo, Japan) with 75ml/min nitrogen flow and 10°C/min of heating rate from 30 to 600 °C. Sample preparation of paraffin actuator Paraffin compounds were prepared from pure N-Eicosane (Melting point 32°C, P1) and N-Eicosane mixed with P1/PAN hybrid nanofiber 2.5%, 5%, 7.5%,10% by weight and named as S2, S3, S4 and S5. Table 3.1. shows detailed information for each prepared sample. A stepwise visual demonstration of sample preparation and hysteresis testing of the paraffin actuator are shown in Figure 3.2.

3.1.2. Working principle of paraffin actuator

A paraffin actuator consists of a sealed stainless steel capsule (4), stainless steel cover (2), stainless steel piston (1), elastomeric diaphragm sealing (3) and paraffin compound (5) as shown Figure 3(a). The paraffin compound is sealed inside the capsule which avoids the leakage of the paraffin to the outside of the capsule during melting/expansion. When the temperature of the medium outside the capsule rises and exceeds the melting point of the paraffin compound of the actuator, the paraffin compound expands and presses against the diaphragm sealing. The movement is transferred to the piston. The cover part guides the movement of the piston into the vertical direction and keeps the diaphragm sealing in upright position. Counter spring pushes the piston back inside the diaphragm sealing if the medium temperature decreases down under the melting point where the paraffin compound shrinks. Volume change of the paraffin compound is converted to displacement of the piston where the opening stroke of the paraffin actuator is recorded by displacement sensor in millimeter. Principle of the thermal hysteresis has been explained in following topic.

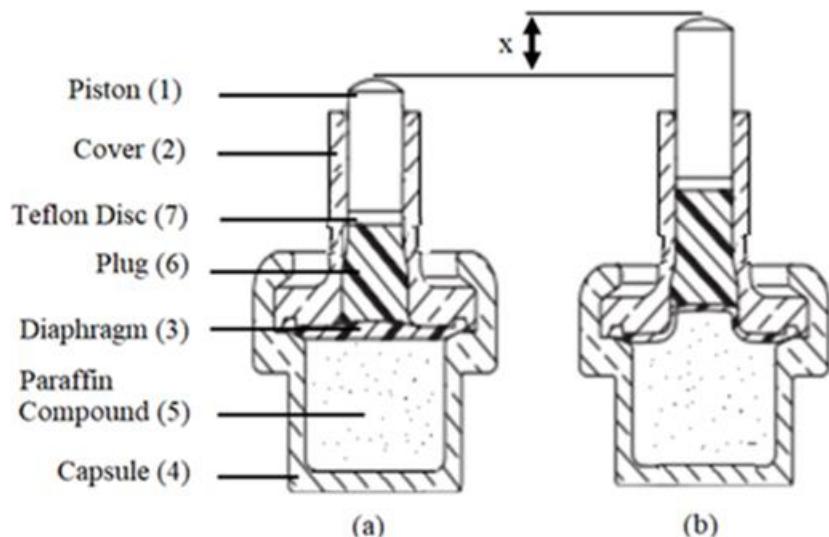

Figure 3.3. Paraffin actuator subcomponents (a) closed paraffin actuator: before heating/displacement of piston, (b) opened paraffin actuator heated - molten expanded paraffin.

3.1.3. Thermal hysteresis of paraffin actuators in terms of volume expansion

Volume expansion of paraffin is upto 15% during phase change from solid phase to liquid phase (Chen et al., 2008). However, temperature depended volume change speed of the paraffin compound lacks of hysteresis. Volume shrinkage speed of solidification is remarkable lower than volume expansion speed of melting at a Paraffin actuator. This thermal hysteresis phenomenon can be observed on piston displacement curve versus heating and cooling of the paraffin actuator in a cooling circuit. External factors, which affect on the expansion performance/thermal hysteresis of the paraffin content, depend on counter force of the spring in the thermostat, heating - cooling speed of the test bath, thermal conductivity of coolant media, circulation speed of the coolant media. Thermal hysteresis is the ΔT of heating-cooling cycle based on temperature-stroke curve at 3mm stroke. Initial stroke zone is the temperature range where the piston is subjected to movement from the rest by means of paraffin expansion via phase change from solid to liquid. After the initial stroke zone, the paraffin actuator performs a relative high opening course until it reaches to full-stroke zone. Full stroke zone is the temperature range where the paraffin expansion ends.

3.1.4. Testing setup for thermal hysteresis

Testing setup consists of paraffin actuator, compression spring, displacement sensor, heated/circulated coolant bath, analog digital converter, electrical resistance heater, K-type thermocouple, circulation pump, temperature programmer, computer/data logger and fixing apparatus for the fixation of the paraffin actuator in the coolant bath. In testing setup, the paraffin actuator is fixed in an apparatus and only the vertical movement of the piston is allowed. A spring having a spring constant (k) of 7N/mm is working against the piston with the initial force of 70N to confine the piston movement during paraffin melting phase change and compressing it in to capsule during solidification. Circulated coolant media is flowing around the capsule for securing the dynamic temperature transfer from coolant to paraffin actuator simulating the coolant flow in the car cooling system. Temperature programmer gives the input for the heating and cooling temperature speed to operate the electrical resistance heater. K-Type thermocouple and displacement sensor record the temperature value and piston stroke

simultaneously where the computer collects these data in a text file for later data processing.

Common specifications for hysteresis require 1°C/min heating up speed and 1°C/min cooling down speed for the paraffin actuator where the thermal bath temperature starts with 5°C before the first movement of the piston and heated until 15°C hereafter. The bath is cooled down with a speed of 1°C/min until the starting temperature (5°C before initial stroke of the piston). At the testing setup, all the affecting external factors are kept (spring force, heating-cooling speed, coolant media, circulation speed) constant and just the alterations of the paraffin compound in the paraffin actuator samples are investigated.

Testing setup is programmed to record into a text file the data of the opening stroke value of the paraffin actuator against temperature change and time interval during the heating and cooling process. A combined Time/ Temperature/Opening curve is plotted from the recorded data into a Microsoft Excel file. Excel Scatter Chart is used to create the hysteresis curve where the opening stroke of the paraffin actuator is depicted according to heating and cooling cycle independent of time interval.

3.2. Thermal Hysteresis Enhancement and Dispersion Thermal Stability

3.2.1. Chemicals and equipments

Polyacrylonitrile and N,N-dimethylformamide, paraffin Nonadecane (P) were supplied identically as detailed in Chapter 3.1.1. CuO with particle size 38nm, Fe₃O₄ with particle size 18.0-28.0nm, Al₂O₃ with particle size 18.0nm and ZnO with particle size 30.0-50.0 nm metal oxide nanoparticles were purchased from Nanografi Nanotechnology AS (Cankaya/Ankara TURKEY).

Table 3.2 shows the properties of metal oxide nanoparticles declared by the manufacturer. Same electrospinning equipments and process parameters are used with that of explained in Chapter 3.1.1.

Table 3.2. Properties of metal oxide nanoparticles declared by the manufacturer.

Nanoparticle	CuO	Fe ₃ O ₄	ZnO	Al ₂ O ₃
Purity (%)	99.99	98.45	99.5	99.5
Color	black	dark brown	milky white	white
Average Particle Size (nm)	38.0	18.0 - 28.0	30.0 - 50.0	18.0
Specific Surface Area (m ² /g)	>20	>55	70	140
True Density (g/cm ³)	6.5	5.1	5.5	3.9

3.2.2. Electrospinning of PAN nanofibers

Firstly, 8 wt.% of PAN in DMF was dissolved by magnetic stirring at an ambient condition in a glass vial. Preparation of PAN nanofiber by using electrospinning method has been investigated by several groups (Gu et al. 2005, Zhang et al. 2014). In this study, 6ml of the prepared solutions were filled into the vial. Then the vial was put on a magnetic stirrer and stirred. The solution was stirred harshly (at 500 rpm). The prepared final solution was filled in the plastic syringes (21-gauge, needle length of 1,5cm).

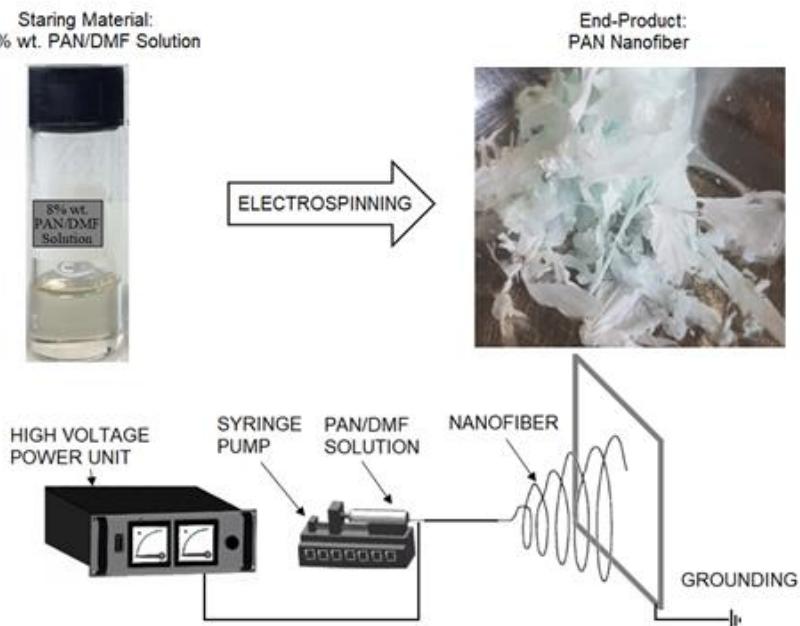

Figure 3.4. Electrospinning of PAN Nanofiber

The Electrospinning was complianced with the process described in capital 3.1.2, here just the polymer solution was prepared without any addition of paraffin. The process is shown in Figure 3.4.

3.2.3. Characterizations of paraffin nanocomposite

Morphological investigations, fiber diameter detection and EDS Analysis were carried out with same methods explained in Chapter 3.1.2.

3.2.4 Paraffin nanocomposite samples preparation

Paraffin nanocomposite samples were prepared with Nonadecane paraffin (Melting point 32°C), paraffin /CuO nanoparticles, paraffin /Fe₃O₄ nanoparticles, paraffin /Al₂O₃ nanoparticles, paraffin /ZnO nanoparticles, paraffin /PAN nanofiber wt.10% and named as N1, N2, N3, N4 and N5.

For each metal oxide nanocomposite sample, 1.8g Nonadecane paraffin is heated to 100°C and 0.2g nanoparticle added to liquid paraffin in one portion. The mixture is harshly stirred with a 13.000 rpm high speed mixer until the nanocomposite is solidified down to 25°C.

Table 3.3 shows detailed information for each prepared sample. Nonadecane /PAN nanofiber nanocomposite is prepared with addition of 0.2g nanofiber into 1.8g Nonadecane at 100°C. Nanofiber/paraffin mixture is smoothly kneaded until solidified and cooled down to 25°C.

All samples are prepared in a separate stainless steel pot. The visual property of the mixtures are also observed where all the paraffin-metal oxide mixtures have shiny color and paraffin-PAN nanofiber has matte color.

Table 3.3. Paraffin nanocomposite samples

Sampl. Name	Picture of the Nanocomposite	Nano- composite	Color	Mixing Type	Weight
N1		CuO / Paraffin	Shiny black- ish	harshly stirred via 13000rpm high speed mixer until solidified	0.2g CuO Nanoparticle/ 1.8g Nonadecane
N2		Fe_3O_4 / Paraffin	Shiny brown -ish	harshly stirred via 13000rpm high speed mixer until solidified	0.2g Fe_3O_4 Nanoparticle/ 1.8g Nonadecane
N3		ZnO / Paraffin	Shiny milky white	harshly stirred via 13000rpm high speed mixer until solidified	0.2g ZnO Nanoparticle/ 1.8g Nonadecane
N4		Al_2O_3 / Paraffin	Shiny white	harshly stirred via 13000rpm high speed mixer until solidified	0.2g Al_2O_3 Nanoparticle/ 1.8g Nonadecane
N5		PAN /Paraffin	Matte white to hell grey	Smoothly kneaded with tweezers until solidified	0.2g PAN Nanofiber / 1.8g Nonadecane

3.2.5. Dispersion thermal stability test (DTST) and sample preparation

Samples are prepared from paraffin nanocomposites N1, N2, N3 N4, N5 and pure nonadecane and named for 45°C storage as L1, L2, L3, L4, L5 and L6, for 100 °C storage as H1, H2, H3, H4, H5 and H6 respectively shown in Figure 3.6.. Table 3.4 shows sample and test information for each test. BD U-100 0.5ml Insulin syringe without plunger is used as test container of thermal stability test where one can see the precipitation through the transparent plastic wall visually. Demonstration of sample preparation and thermal stability testing paraffin nanocomposites are shown in Figure 3.5.

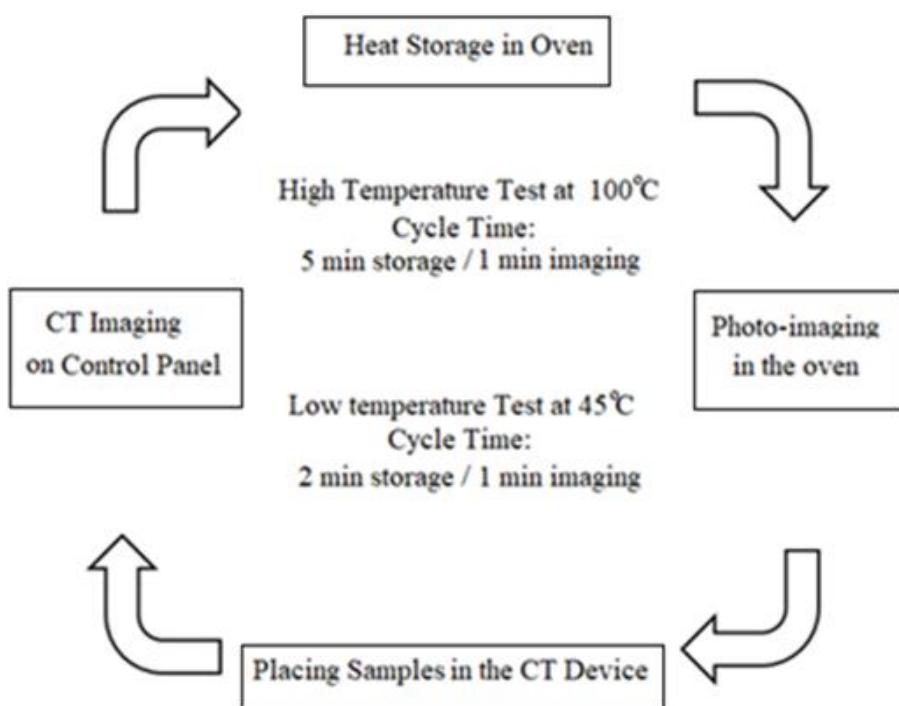

Figure 3.5. Dispersion thermal stability test setup

Dispersion thermal stability tests are performed by storing the samples at certain temperature in Nukleon NST120 Oven. The sample contents prepared for tests are listed in Table 3.4. In Figure 3.5 shown test samples are fixed in a special jig and put into the oven for a given time at certain temperature. High temperature test is done to observe the fully precipitation of nanoparticles at 100°C which is well above the melting point.

The duration of high temperature storage where the fully precipitation occurred, is used as basic time information for the second level test of hysteresis for paraffin actuators.

Table 3.4. Properties of DTST Samples

Content	Sample Name	Nanocomposite in use	Sample Weight
CuO	L1 and H1	N1	0.570g
Fe ₃ O ₄	L2 and H2	N2	0.550g
ZnO	L3 and H3	N3	0.550g
Al ₂ O ₃	L4 and H4	N4	0.545g
PAN	L5 and H5	N5	0.540g
Nonadecane	L6 and H6	pure paraffin	0.520g

Low temperature dispersion thermal stability test is performed at 45°C which corresponds the top temperature of hysteresis cycle and indicating the dispersion morphology of nanocomposite during heating up of the paraffin actuator. The samples stored in the oven are subjected to periodical inspection at Computer Tomography (CT) YXLON Y.MU2000-D for storage at 100°C after every 5 minutes and for storage at 45°C after every 2 minutes. Both storage tests were completed after 20 minutes. The density of nanocomposite changes as the paraffin melts and the nanoadditives precipitates. The darkness distribution of the CT-imaging determines the density homogeneity and precipitation of the nanoparticles in nanocomposites respectively. Test periods of dispersion thermal stability test are listed in Table 3.5.

Table 3.5 DTST Periods

Test Name	100°C Storage	45°C Storage
Samples tested	H1, H2, H3, H4,H5,H6	L1, L2, L3, L4, L5, L6
Test Duration	20min	20 min
Inspection Period	5min	2 min

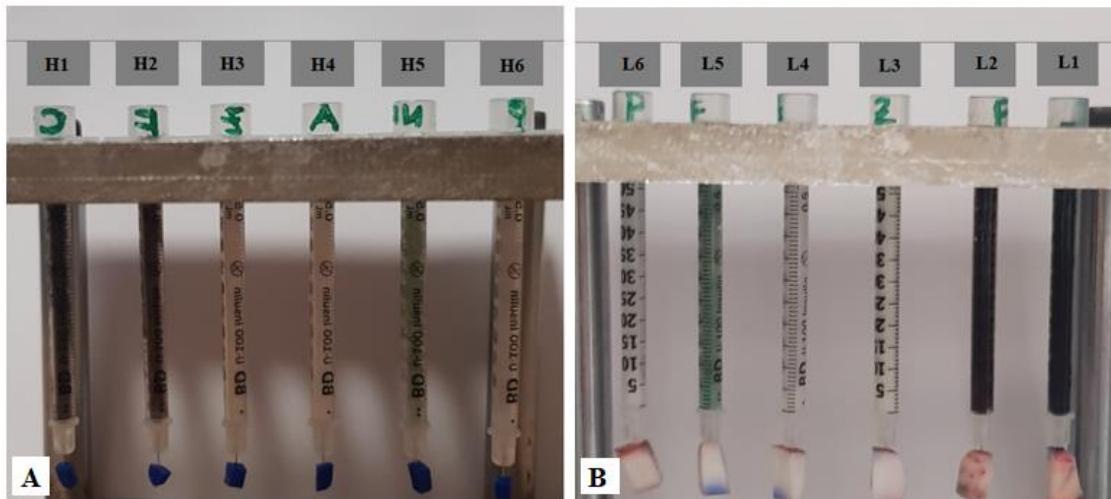

Figure 3.6. A) High temperature DTST samples H1: CuO-Paraffin, H2: Fe_3O_4 -Paraffin, H3: ZnO-Paraffin, H4: Al_2O_3 -paraffin, H5: PAN-paraffin, H6: pure paraffin, B) Low temperature DTST samples L1: CuO-Paraffin, L2: Fe_3O_4 -Paraffin, L3: ZnO-Paraffin, L4: Al_2O_3 -paraffin, L5: PAN-paraffin, L6: pure paraffin

3.2.6. Thermal hysteresis test and paraffin actuator sample preparation

A stepwise visual demonstration of sample preparation, hysteresis testing and working principle of paraffin actuator are explained in detail at our previous research (Kutlu et al. 2021). A paraffin actuator consists of a sealed stainless steel capsule, stainless steel cover, stainless steel piston and elastomeric diaphragm sealing and paraffin compound. The paraffin compound sealed inside the capsule which avoids the leakage of the paraffin to the outside of the capsule during melting/expansion. When the temperature of the medium outside the capsule rises and exceeds the melting point of the paraffin compound of the actuator, the paraffin compound expands and presses against the diaphragm sealing. The movement is transferred to the piston. The cover part guides the movement of the piston into the vertical direction and keeps the diaphragm sealing in upright position. Counter spring pushes the piston back inside the diaphragm sealing if the medium temperature decreases down under the melting point where the paraffin compound shrinks. Volume change of the paraffin compound is converted to displacement of the piston where the opening stroke of the paraffin actuator is recorded by displacement sensor in millimeter. Testing setup for thermal hysteresis is a replication that of previous work. (Kutlu et al. 2021).

Hysteresis test was performed with 1°C/min heating up speed and 1°C/min cooling down speed from 25°C to 45°C coolant bath temperature. At the testing setup, all the affecting external factors are kept constant and just the alterations of the paraffin nanocomposite in the paraffin actuator samples are investigated.

At recent investigation, two levels hysteresis test is performed and sample annotation regarding the test is listed in Table 3.6. At first test level, hysteresis of all paraffin actuator samples P1, P2, P3, P4, P5 and P6 are depicted with paraffin actuators made of as mixed and solidified nanocomposite where no precipitation is occurred. After first level test, all the paraffin actuator samples were stored in an oven at 100°C. The duration of this high temperature storage was determined by the high temperature dispersion thermal stability test results in which almost all the metal oxide nanoparticles deposited to the bottom. Thereafter a second level test was performed with these paraffin actuator samples to ascertain the precipitation effect on thermal hysteresis, conceivably to verify the avail of nanofiber-paraffin nanocomposite which scarcely precipitates.

Table 3.6. Properties of Paraffin Actuator Samples

Content	Sample Name	Nanocomposite in use	Sample Weight
CuO	P1	N1	0.470g
Fe ₃ O ₄	P2	N2	0.460g
ZnO	P3	N3	0.460g
Al ₂ O ₃	P4	N4	0.455g
PAN	P5	N5	0.450g
Nonadecane	P6	pure paraffin	0.440g

3.3 Effect of the Number of Carbon in Paraffin on Interaction with Nanofibers

Conventional electrospinning method was applied to produce nanofibers (Huang et al., 2003), (Lackowski et al., 2013), (Liu et al., 2019). 7,5% of PVA was dissolved in distilled water at THINKE ARE-250 Planetary Mixer by 200rpm speed and 20 minutes

at the ambient condition. The dissolved solution was filled in a plastic syringe which has a metal hollow needle (0.5 mm inner diameter). The syringe was put in front of a grounded collector that covered with aluminum foil. The distance between the tip of the needle and the collector was adjusted to 15 cm. PVA nanofibrous mat structure on the aluminum foil by applying 15 kV voltage to the metal needle and feeding the solution with 1 ml/hrs to the existence of the needle. Liquid paraffin was interacted with the nanofibers by electrospraying them on the nanofibrous mat structures. Morphological analysis of the PVA fibers and PVA/paraffin systems were performed with optical microscopy Zeiss Axio Vert.A1, thermal analysis was conducted with a differential scanning calorimeter TA/Discovery DSC250, and wettability was investigated by Attension Theta contact angle measurement device.

Liquid paraffin is accumulated /deposited on nonwoven nanofiber structure as a composite layer via electrospraying. Microscopic analysis of PVA/paraffin system, and interaction of paraffin with PVA nanofiber mat surface was investigated by performing contact angle measurement. Following three different types of paraffin pentadecane, hexadecane, and heptadecane were used for wettability study.

4. RESULTS and DISCUSSION

4.1 Paraffin/PAN Hybrid Nanofibers for Thermal Hysteresis Enhancement

Morphological observation of P/PAN nanofibers due to paraffin type and amount morphology analysis of as-spun paraffin loaded P/PAN nanofibers were carried out via electron microscopy imaging due to the both paraffin content (Figure 4.1) and type of the paraffin (Figure 4.2) at P/PAN nanofibers. As seen from Figure 4.1 (A1, A2, a), pure PAN nanofibers exhibited a random distribution in the mat, highly uniform nanofibers were obtained, just a few negligible bead defect structure was observed. Since some paraffin particles were stayed in the solution in suspension form, these particles mostly in sphere forms were directly ejected on the nanofibers and were seen on the nanofibers mat surface at low magnification SEM images as seen in Figure 4.1 (B1) to (D1). The mentioned spherical particles were not observed at low magnification SEM image of pure PAN nanofibers in Figure 4.1 (A1). On the other hand, also bead-on-a-string morphology defect structure was observed by the addition of paraffin in P/PAN nanofiber as seen from the inset Figures in Figure 4.1 (B1) to (D1). The amount of bead-on-a-string morphology defect structure in the nanofiber mats increased by increasing paraffin ratio in electrospinning solution (inset Figures in Figure 4.1 (B1) to (D1)). Even though the electrospinning process was applied at the ambient condition and the paraffins in the solutions were in solid state, Figure 4.1 (C3) revealed that some paraffin particles were melted during the electrospinning and solidified when they reached on the nanofiber surface, and these melted paraffin bonded the fibers by solidification. During the electrospinning process, some sparks can be seen because of high voltage electricity. These sparks may have melted some paraffin. Another reason for the formation of this structure may be that some paraffin particles melt during the sputter coating (during the SEM sample preparation) and then bonded to the fibers after solidification. Nanofiber diameters were measured from selected 100 nanofibers in SEM images and diameter distribution chart graphics were given in Figure 4.1 (A3) to (D3) with average nanofiber diameters. As seen from the graphs, most of the pure PAN fibers have the diameters ranging between 300-500 nm. The diameter tendency shifted to lower values with the addition of paraffin, and nanofibers had the diameter range

between 150 and 300, 150 and 300, 100 and 250nm for samples P3/PAN-1, P3/PAN-2 and P3/PAN-3 respectively. Average nanofiber diameter in PAN nanofibers mat was measured as 376 nm. Average nanofiber diameter decreased with the addition of paraffin into PAN nanofibers, and the counted average fiber diameters were 220, 241 and 214nm for samples P3/PAN-1, P3/PAN-2 and P3/PAN-3 respectively.

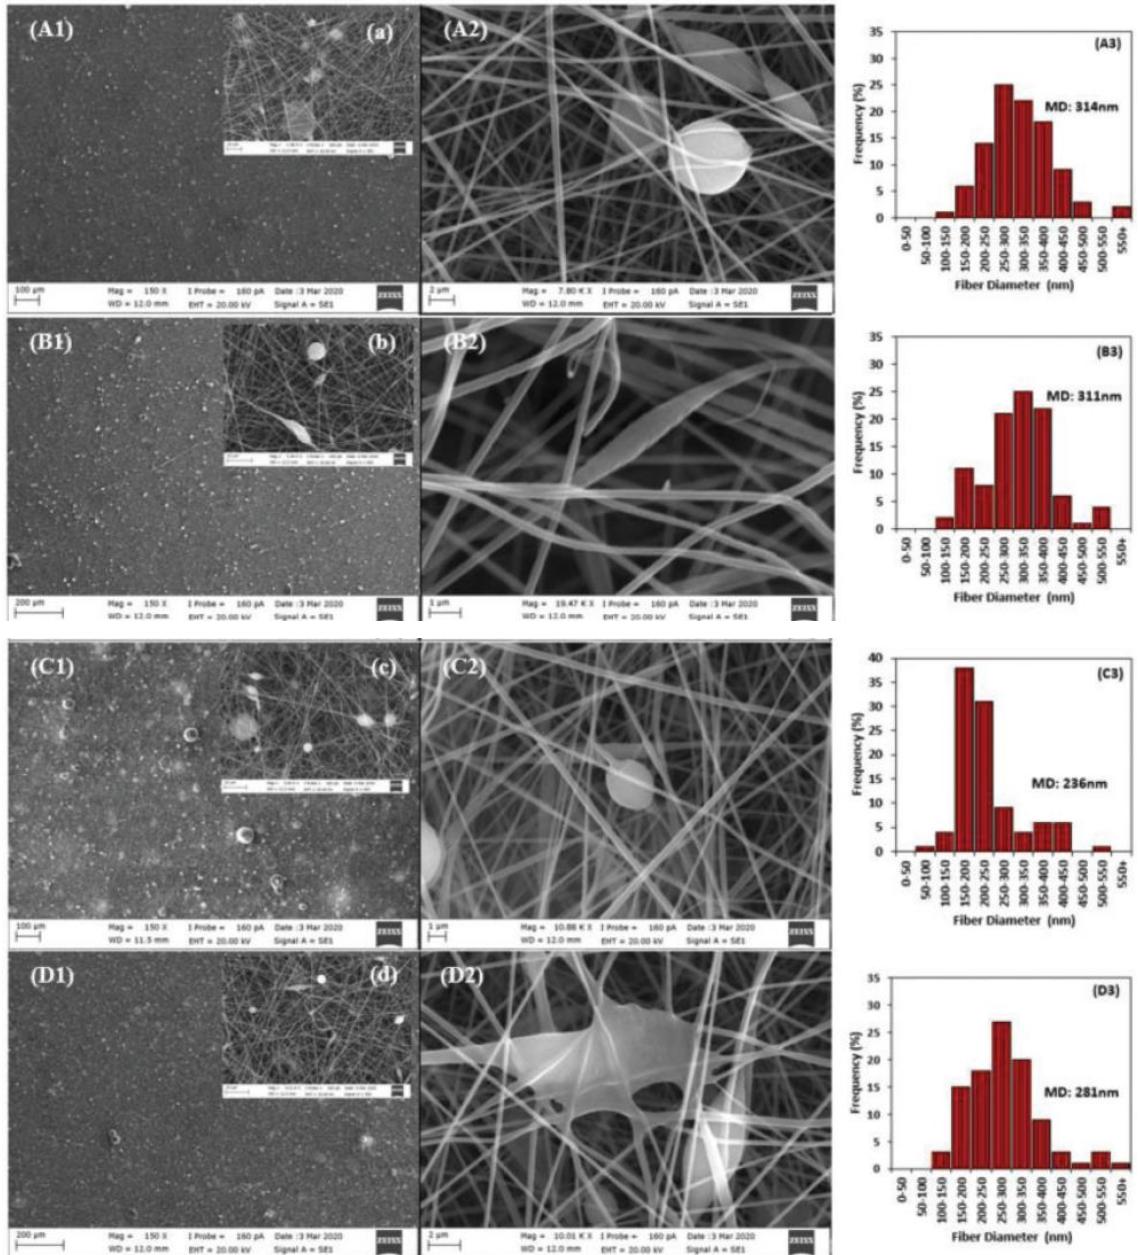

Figure 4.1. SEM images of P/PAN hybrid nanofibers (depending on paraffin type): (a) P1/PAN, (b) P2/PAN, (c) P3/PAN and (d) P4/PAN.

SEM images of P/PAN nanofibers due to paraffin types were shown in Figure 4.1. Nanofiber diameter distribution chart graphics with the average nanofiber diameters of different paraffin type P/PAN nanofibers were demonstrated in Figure 4.1 (A3) to (D3). As seen from the graphs, the fiber diameter distributions were various depending on paraffin type. Sphere type particles were observed on the surface of nanofibrous mat at all the sample types as seen from the low magnification SEM images in Figure 4.1 (A1) to (D1). Some little beaded defect structures were also seen in all types of paraffin additions. Nanofibers have the diameter range mostly between 250-400, 250-400, 150-300 and 200-350nm for samples P1/PAN, P2/PAN, P3/PAN and P4/PAN respectively. Average nanofiber diameter in PAN nanofibers mat was measured as 376 nm. Average nanofiber diameter decreased with the addition of paraffin into PAN nanofibers, and the counted average fiber diameters were 314, 311, 236 and 381 nm for samples P1/PAN, P2/PAN, P3/PAN and P4/PAN respectively.

Chemical analysis of pure PAN and P/PAN nanofibers due to paraffin type and amount was conducted via FTIR analysis to investigate if there was any chemical change in the nanofibers. Firstly, the chemical structure of the pure paraffins used in the study were observed as seen in Figure 4.2 (a). The same amount of these paraffins were added in the same concentration of PAN/DMF solution.

Effect of the amount of paraffin in P/PAN nanofiber mats were analysed and the results were shown in Figure 4.2 (b). Nanofibers were produced by electrospinning and chemical analysis of P/PAN nanofibers depending on paraffin types were demonstrated in Figure 4.2 (c). As seen from Figure 4.2 (a), the prominent paraffin peaks detected around $715\text{--}719\text{ cm}^{-1}$ were attributed to inplane vibration of CH_2 groups (Zhang et al., 2019), (Haghighe et al., 2018). The peaks between 729 and 731 cm^{-1} could be attributed to rocking absorbtion band of lineer aliphatic structure of paraffin (Varshney et al., 2012) . The peak between 1452 and 1462 cm^{-1} corresponds to scissoring mode of CH_2 groups [35], $1469\text{--}1471\text{ cm}^{-1}$ assigned to C-H bending vibration (Zhang et al., 2019) and $2912\text{--}2914\text{ cm}^{-1}$ corresponds to CH_2 asymmetric stretching (Chaber et al., 2017). The peak 2947 cm^{-1} is related to C-H stretching vibrations of CH_3 groups (Nie et al., 2015) , and the peak at 2955 cm^{-1} assigned to asymmetric stretching of CH_3 groups

(Chaber et al., 2017). Additionally, the symmetric carbon-hydrogen bending absorption of the CH_3 groups are detected at 1371 cm^{-1} for P1 and 1377 cm^{-1} for P2 and P3 samples (Varshney et al., 2012).

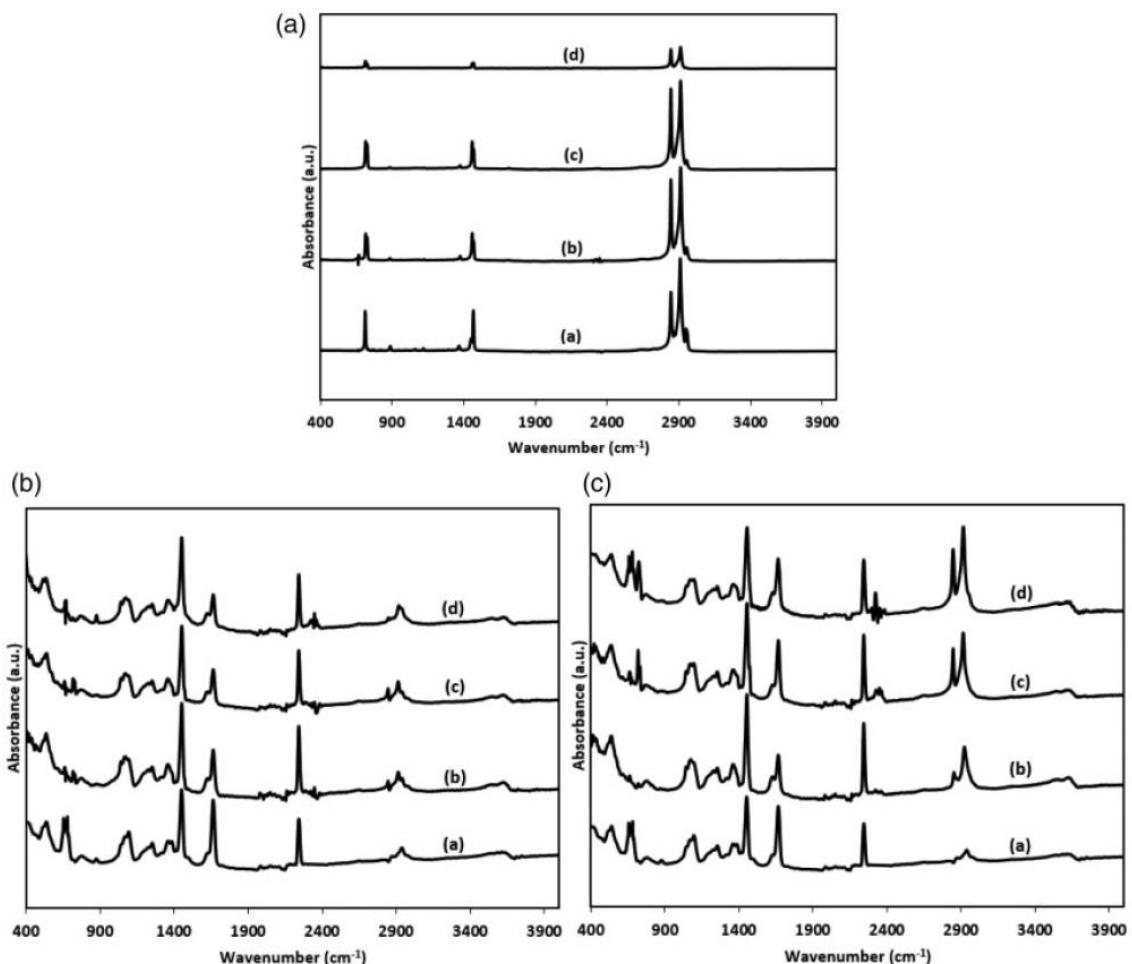

Figure 4.2. FTIR spectra of (a) pure paraffins (a) P1, (b) P2, (c) P3 and (d) P4; (b) P/PAN nanofibers with different paraffin concentration (a) just PAN, (b) P3/PAN-1, (c) P3/PAN-2 and (d) P3/ PAN-3; and (c) P/PAN nanofibers with different paraffin types (a) just PAN, (b) P1/PAN, (c) P2/ PAN, (d) P3/PAN and (e) P4/PAN.

FTIR spectrum of pure PAN nanofibers were demonstrated in Figures 4.2(b) and (c) as inset plots indicated by “a”. Prominent peaks for pure PAN nanofibers were detected at 1359 , 1450 , 1664 , 2243 and 2939 cm^{-1} . C-H wagging of methyl groups was detected at 1359 cm^{-1} (Badii et al., 2016) and bending vibrations of methylene groups were observed at 1450 cm^{-1} (Ji et al., 2009). The peak at 1664 cm^{-1} could be related to trapped residual non evaporated DMF solvent (Tighilt et al., 2007). Stretching vibration of C-N

nitrile functional group was observed at 2243 cm^{-1} (Chen et al., 2008), (Varshney et al., 2012) . C-H stretching vibration was seen at 2939 cm^{-1} (Cetin and Camurlu, 2018). As seen from Figure 4.2.(c), when the FTIR spectra was inspected by the addition of different melting point paraffins to PAN nanofibers, the peak intensities at 2847 and $2912\text{--}2614\text{ cm}^{-1}$ were significantly increased with all types of paraffin additions to PAN nanofibers revealing the existence of paraffins in the structure. Intensities of these peaks were not proportionally changed by changing paraffin contents in P/PAN nanofibers (Figure 4.2(b)). This implied that either the paraffin content didn't increase proportionally in P/PAN nanofibers or the distribution of the paraffin in the nanofibers or mat were not homogeneous. Even though the paraffin content was increased proportionally in the electrospinning solution, since the final paraffin suspensions were not homogeniously distributed in the solution and there should have been some paraffin precipitation in the plastic syring during the electrospinning process. The intensities of paraffin peaks were not in a proportional orders due to their rate in P/PAN nanofibers. These positions of the corresponding peaks coming from PAN molecules in P/PAN nanofibers as in Figure 4.2(b) didn't change significantly comparing PAN nanofibers. This revealed that there was not a chemical interaction between PAN and paraffin molecules both at solution and nanofiber preparation processes. So, the phase transition property of paraffin could be very applicable for the cyclic usage.

Differential scanning calorimeter measurements were carried out to observe melting points (T_m) and enthalpies of the pure paraffins (Figure 4.3(a)) and paraffin loaded P/PAN nanofibers (Figure 4.3(b) and (c)). As seen from Figure 4.3(a), single melting peaks (T_m) were detected at 38.5, 89.9 and 114.7°C for the samples P1, P3 and P4. Sample P2 demonstrated two distinct melting peaks located at 58.6 and 69.5°C . They revealed that this sample could have contained two different crystalline structures. Since these two peaks are coalesced, both peaks were considered for the enthalpy determination of the sample. Producing P/PAN nanofibers with different concentration of the same type of paraffin didn't change the melting point of

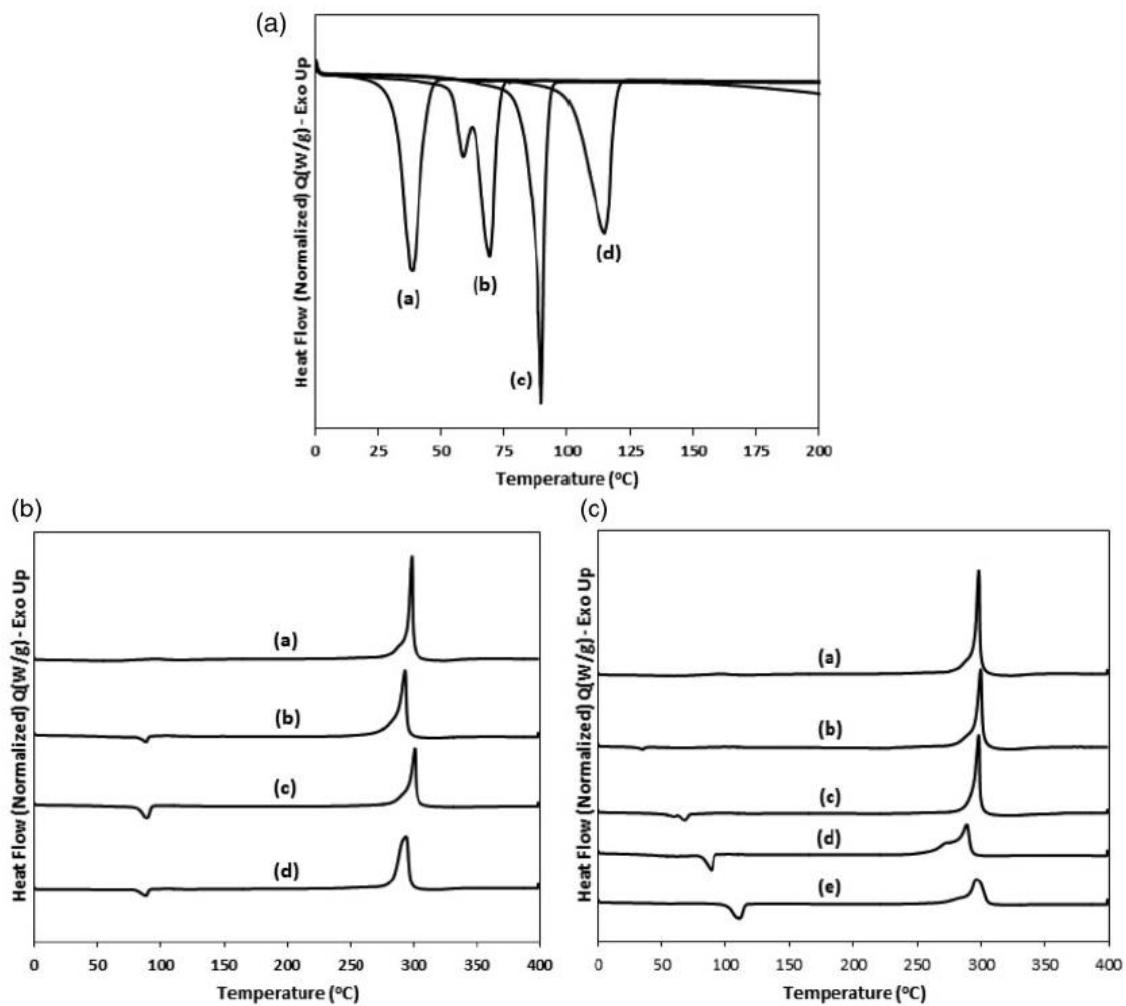

Figure 4.3. DSC of neat paraffins and P/PAN nanofibers: (a) pure paraffins (a) P1, (b) P2, (c) P3 and (d) P4; (b) P/PAN nanofibers with different paraffin concentration (a) just PAN, (b) P3/PAN-1, (c) P3/PAN-2 and (d) P3/PAN-3; and (c) P/PAN nanofibers with different paraffin types (a) just PAN, (b) P1/PAN, (c) P2/PAN, (d) P3/PAN and (e) P4/PAN.

Producing P/PAN nanofibers with different concentration of the same type of paraffin didn't change the melting point of paraffin part in the nanofibers distinctively as demonstrated in Figure 4.3(b). The positions of melting points of paraffins were shifted when they were loaded with different paraffin types and produced in the form of P/PAN nanofibers. The detected paraffin melting points in P/PAN nanofibers were 34.5, 88.3 and 110.7°C for P1/PAN, P3/PAN and P4/PAN samples respectively (Figure 4.3(c)). Melting points were shifted to 59.8 and 88.3°C for P2/PAN and P3/PAN sample as shown in Figure 4.3(c). As seen, melting points of paraffins decreased for P1, P3 and P4

samples when the paraffin was loaded to PAN nanofibers as in P1/PAN, P3/PAN and P4/PAN. Even though the first detected melting point of P2/PAN increased to 59.8°C, the second detected melting point decreased to 67.8°C. As seen from Figure 4.3(b) and (c), a strong exothermic peak was detected at 298.1°C for pure PAN nanofiber. This peak is related to complex chemical reaction (dehydrogenation, cyclization, and cross-linking) (Zhu et al., 2003) taking place at PAN molecules in the nanofibers. The position of this peaks didn't increase or decrease consistently with either paraffin type or with the amount of paraffin in P/PAN nanofibers (Figure 4.3(b)). But the intensity of the peak decreased with increasing melting point of added paraffin (Figure 4.3(c)). The reduction of the peak could be related to the stronger interaction of paraffin and PAN molecules compared to pure PAN nanofibers (Ji et al., 2008).

Melting enthalpy (DH_m) of the pure paraffins obtained from the DSC plots were 231.1, 219.7, 242.0 and 233.9 J/g for P1, P2, P3 and P4 samples respectively as demonstrated in Figure 4.3(a). The results showed that melting enthalpy did not change consistently due to increase of melting point of the paraffins (Figure 4.3(b)). When the same amount of weight but different type of the paraffins were included in P/PAN nanofibers, melting enthalpy increased with increasing melting point of the paraffin as in Figure 4.3(c). The measured enthalpies of paraffin parts in P/PAN nanofibers were 9.6, 51.9, 64.2 and 101.5 J/g for P1/PAN, P2/PAN, P3/PAN and P4/PAN samples respectively as in Figure 4.3(c). But melting enthalpy differences were not consistent at P/PAN nanofibers when changing the amount of paraffin addition in the electrospinning solution (Figure 4.3(b)). Melting enthalpy of pure PAN nanofibers was measured as 298.1 J/g. The melting enthalpy of PAN nanofibers did not change consistently with the addition of paraffin type and rate.

TGA measurements at the temperature range between 30 and 600°C in nitrogen atmosphere were conducted in order to observe the thermal stabilities and weight losses of pure paraffin, PAN and P/PAN nanofibers. The results of TGA measurement were presented in Figure 4.4. As shown in Figure 4.4(a), only one step weight loss was observed for all paraffin types and the weight loss was related to volatilization of paraffin (Memon et al., 2015). TGA results of pure PAN and P/PAN nanofibers were

given in Figure 4.4(b) for different paraffin concentrations and in Figure 4.4(c) for different paraffin types. First weight loss mainly began around 100°C and made a plateau at around 134°C corresponding to water loss from the nanofibers. Since mostly PAN part held water molecules, the release of water was higher at pure PAN nanofibers comparing to P/PAN nanofibers as seen at inset in Figure 4.4(b) and (c). Release of excess DMF from the fibers started at the beginning of the test. Weight loss mostly took place between 295 and 471°C. The weight loss at PAN nanofibers could be related to chemical reactions taking place in PAN molecules and removal of volatilities

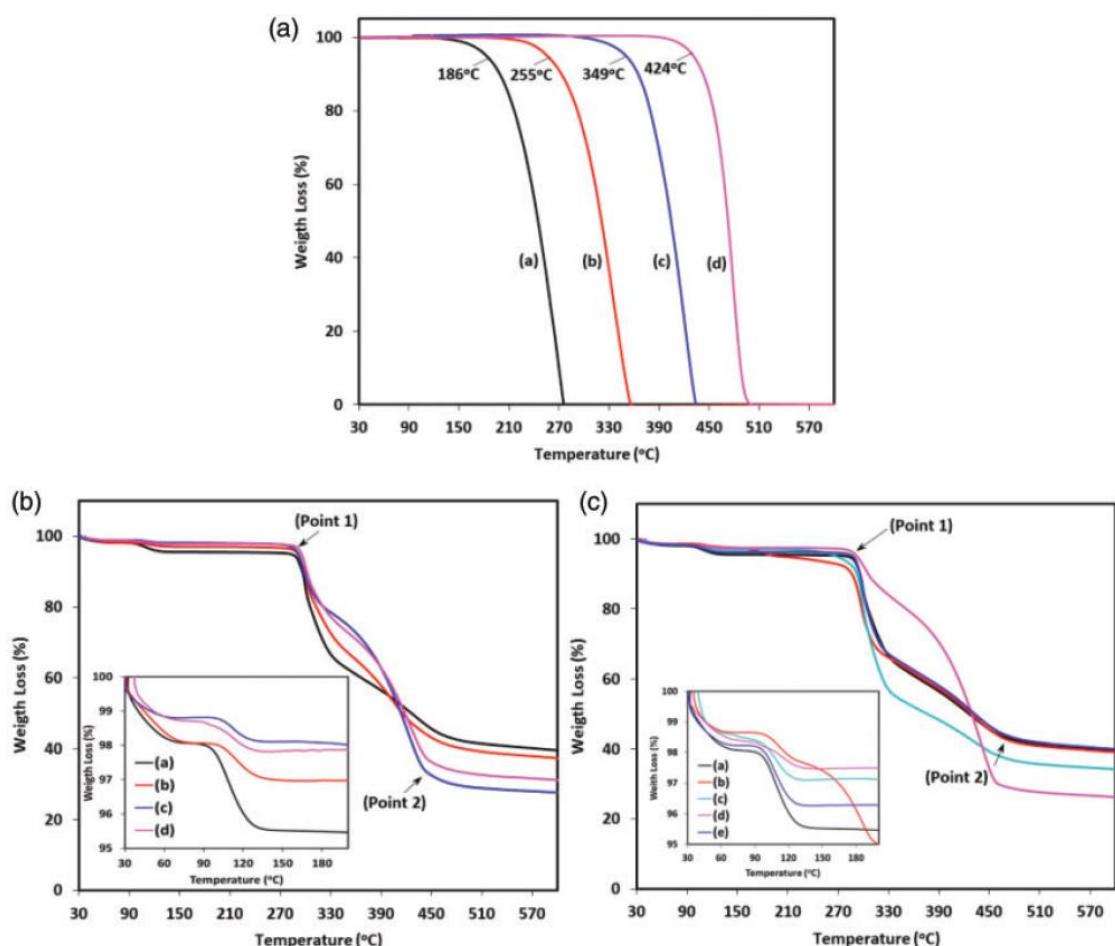

Figure 4.4. Thermogravimetric analysis (TGA) plots of (a) pure paraffins (a) P1, (b) P2, (c) P3 and (d) P4; (b) P/PAN nanofibers with different paraffin concentration (a) just PAN, (b) P3/PAN-1, (c) P3/PAN-2 and (d) P3/PAN-3; and (c) P/PAN nanofibers with different paraffin types (a) just PAN, (b) P1/PAN, (c) P2/PAN, (d) P3/PAN and (e) P4/PAN.

from the system. Similar weight loss plot has been reported in the literature by conducting TGA examination of PAN nanofiber in the nitrogen environment (Onwudiwe et al., 2015), (Wu et al., 2012).

As seen from TGA plots in Figure 4.4(b), weight losses mostly started earlier at P/PAN nanofibers especially when low melting point paraffins were loaded. This could be related to the evaporation of paraffins before the starting degradation temperature of PAN. The residual percentage of pure PAN nanofibers after TGA measurements at 600°C was 39.2 wt.%. Except the sample P4/PAN, the residuals of P/PAN nanofibers decreased comparing to pure PAN nanofiber sample. The residuals of the different type of paraffin loaded P/PAN samples after TGA measurements under nitrogen atmosphere were 38.7, 33.9, 26 and 39.5% respectively for P1/PAN, P2/PAN, P3/PAN and P4/PAN nanofiber samples.

In this work, it was aimed to produce a paraffin-PAN hybrid nanocomposite which is compatible for simply mixing in paraffin compound of paraffin actuator by its nano-sized impregnated/encapsulated paraffin portion. Moreover, the PAN nanofiber portion of the nanocomposite is meant to carry the thermal properties of PAN-nanofibers as a thermal network into paraffin actuator. The investigation started with P3 paraffin in different mixing proportions with PAN polymer. The goal was to ensure the best suitable mixing range of PAN and paraffin molecules. It was found experimentally that the best applicable proportion for mixing and electrospinning process was 50% PAN polymer and 50% paraffin for the hybrid nanofiber synthesis. Especially higher paraffin proportions were found to cause difficulties during electropinning. Further hybrid nanofibers with paraffins of different melting points were produced to confirm the compliance of this simple process for a wide range of paraffin types. Among these paraffin types, DSC results showed that P1/PAN hybrid nanofiber had literally lowest melting enthalpy in comparison with pure paraffin. This throughput indicated that the thermal behaviour of the P1/PAN nanocomposite inclined to thermal properties of PAN portion rather than paraffin portion of hybrid structure. In terms of melting enthalpy of DSC results the other samples (P2/PAN P3/PAN and P4/PAN) inclines to thermal properties of paraffin portion of nanocomposite.

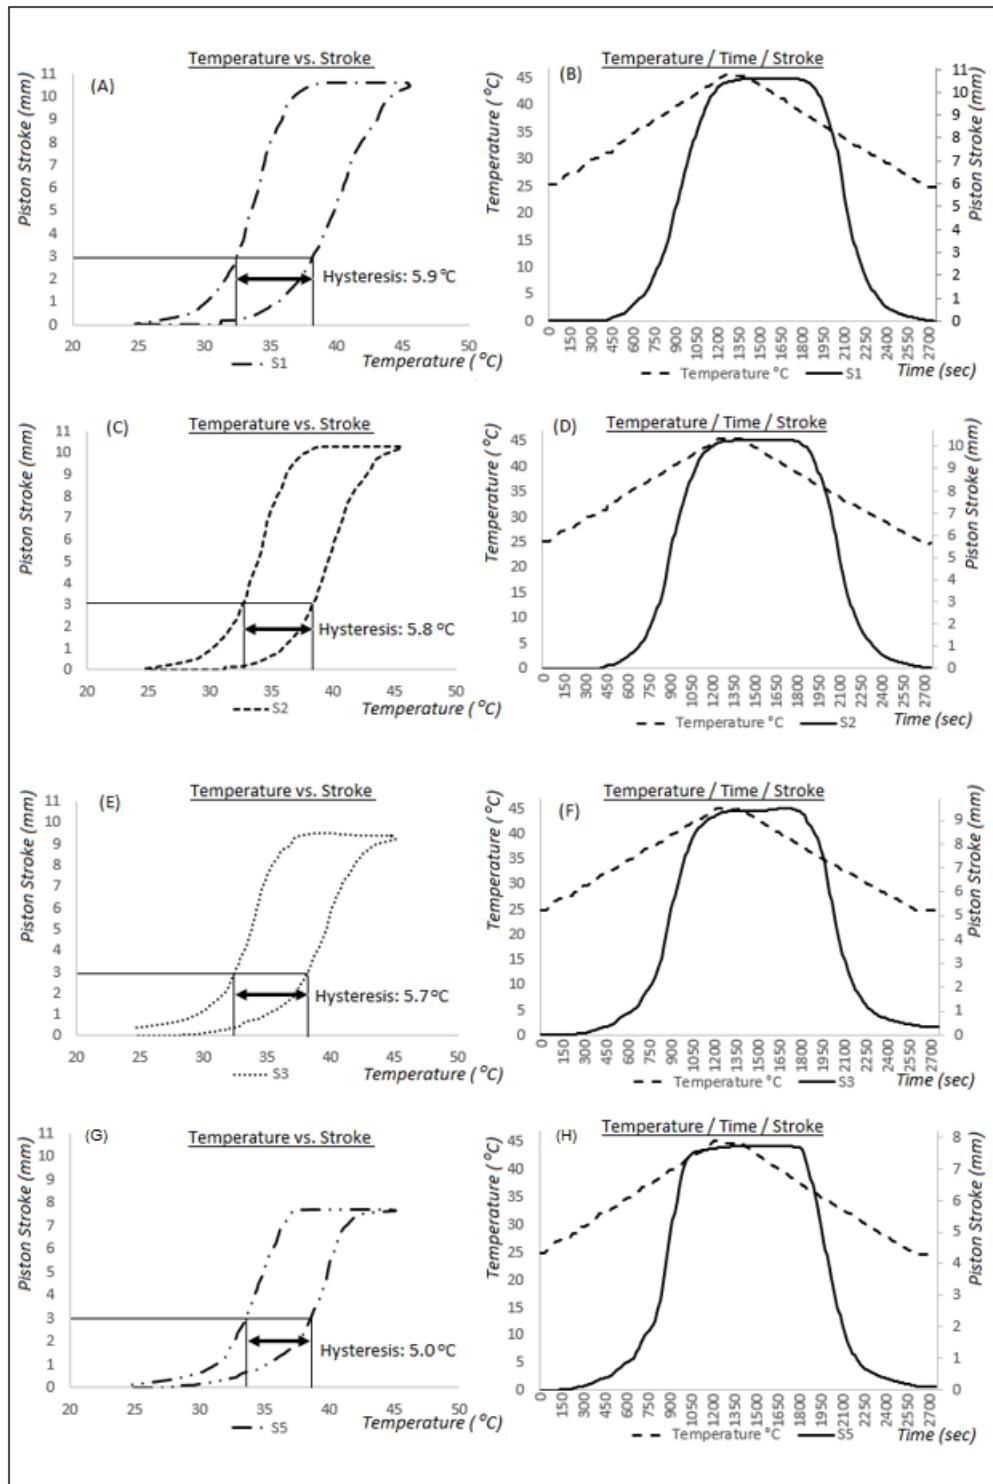

Figure 4.5. Temperature/Time/Stroke Curves and time independent Temperature/Stroke Curves for the samples a) and b) for S1, c) and d) for S2, e) and f) for S3, g) and h) for S4, i) and j) for S5.

Under this circumstances, we have incorporated P1/PAN hybrid nanofiber in paraffin actuator application whose melting temperature is truly suitable for thermal management of e-vehicle batteries cooling systems.

Hysteresis of the paraffin actuator was affected by adding nanofiller into paraffin compound as indicated in Figures 4.5 and 4.6. Hysteresis results according to samples were listed in the Table 4.1 . Increase of the nanofiber amount in the paraffin compound improved the hysteresis in a direct proportional way. Figure 4.7(a) depicts the trend of hysteresis change according to nanofiber addition amount. The highest improvement of hysteresis was recorded at S5 with the 10% of P1/PAN hybrid nanofiber ratio by weight. Hysteresis enhancement up to 15.3% was achieved. In Figure 4.5 from A to J depicted temperature/stroke curves and temperature/stroke/time curves for all samples S1, S2, S3, S4 and S5 separately.

In the paraffin actuator, addition of 2.5 and 5% nanofillers improved the hysteresis moderately up to 3.4% while the addition of 7.5 and 10% nanofillers indicated a jump up to 15,3% hysteresis improvement compared with pure paraffin. This jump demonstrated the thermal percolation threshold effect of the nanofibers in paraffin actuator.

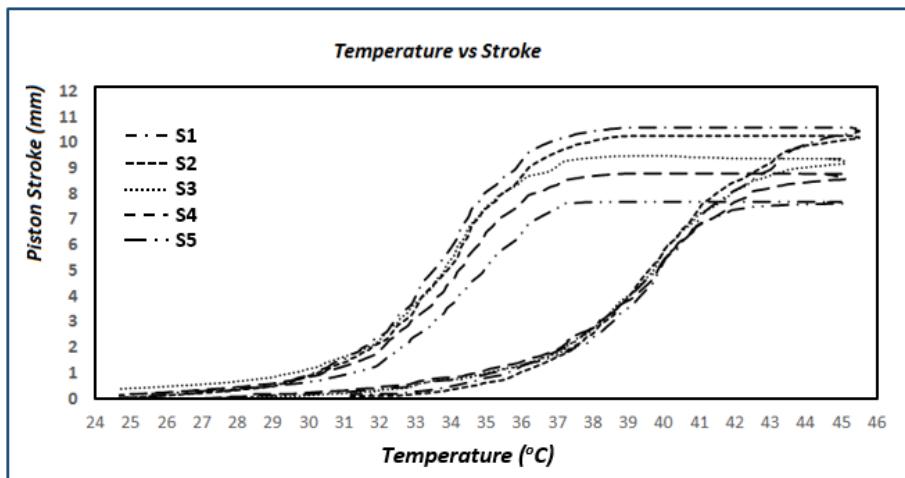

Figure 4.6. Temperature vs Stroke curves of the samples S1, S2, S3, S4, and S5 on the same graph for the comparison.

A substantial nanofiber network with highly inter fiber connections formed especially at the samples of S4 and S5 with nanofiber content of 7.5 and 10%. This feature complied with the findings of the investigation of Tian and Yang on Phonon Transport and Thermal Conductivity Percolation in Nanocomposites and can be explained as follows (Tian and Yang 2008). At the paraffin actuators S2 and S3 with low volumetric concentration of high thermal conductivity constituent, percolation network could not be formed and the thermal conductivity of the composites was effectively controlled by the low thermal conductivity constituents (hereby paraffin proportion) and phonon-interface scattering. When the volumetric concentration of high thermal conductivity constituents (hereby nanofiber proportion) is higher than the percolation threshold as seen at paraffin actuators S4 and S5, geometrically percolate channels for phonon transport is formed (Tian and Yang 2008). This structure allowed the paraffin actuator to achieve the hysteresis enhancement jump at sample S3 by 3.4%, at sample S5 by 11.9%.

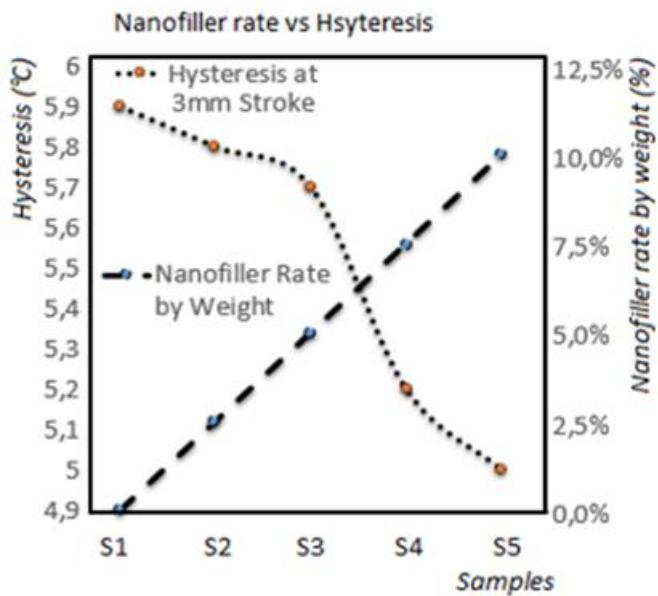

Figure 4.7. Change in Hysteresis according to nanofiller rate by weight of 5 paraffin actuator samples

In Figure 4.7, it can be seen that the opening curves of the 5 samples are very close to each other during the paraffin phase change from solid to liquid at heating cycle. Thermal conductivity of solid paraffin is higher than thermal conductivity of liquid

paraffin. This trend proved the thesis of Mamunya et al that short of high thermal conductivity contrast ratio was postulated to be the main reason for the lack of the thermal conductivity percolation in composite materials (Mamunya et al., 2002). The contrary closing curve of the 5 samples were dissociating from each other during cooling cycle where the liquid paraffin changed to solid phase. Thermal conductivity of n- Eicosane k solid is slightly over 0.350W/m K and k liquid is close to 0.150W/m K. Literally, thermal conductivity contrast between nanofiller and n-Eicosane increased 2.33 times because of the thermal conductivity loss during phase change

Table 4.1. Paraffin actuator hysteresis test results due to nanofiller content

Hysteresis enhancement (%)							
Hysteresis at 3 mm stroke (°C)							
Heating temperature at 3 mm stroke (°C)							
Cooling temperature at 3 mm stroke (°C)							
Full-stroke at 45°C (mm)							
S1	100	0	10.59	32.3	38.2	5.9	0
S2	97.5	2.5	10.26	32.6	38.4	5.8	1.7
S3	95	5	9.49	32.5	38.2	5.7	3.4
S4	92.5	7.50	8.78	32.9	38.1	5.2	11.9
S5	90	10	7.70	32.5	38.5	5.0	15.3

The total paraffin compound filling capacity of the paraffin actuator capsule was 440 mg. The paraffin content of the paraffin compound was reduced and nanofiller was added gradually with following nanofiller/paraffin (mg/mg) amounts of 0/440, 11/429, 22/418, 37/403 and 44/396. Thus the expandable phase change material was replaced with nanofiller, and so the full stroke amount decreased accordingly.

Figure 4.8 depicts a relative change of full stroke amount parallel to sample preparation of paraffin compound. Nanofiller addition had a positive effect on thermal performance of the paraffin actuator but a stroke loss up to %27 was observed with 10% nanofiller addition. Full stroke amount of each sample at 45°C are listed at Table 4.1. The capsule

inner volume of the paraffin actuator should be increased in accordance with the nanofiller addition if the stroke loss needs to be eliminated for a specific application area.

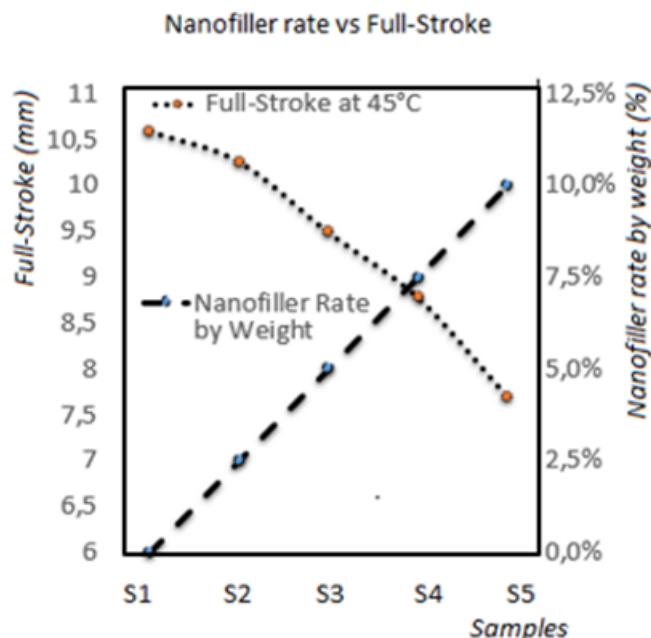

Figure 4.8. Change in full stroke at 45 C nanofiller rate by weight for 5 paraffin actuator samples.

4.2. Thermal Hysteresis Enhancement and Dispersion Thermal Stability

4.2.1. Morphological observation of PAN nanofibers

Morphology analysis of as-spun PAN nanofibers was carried out via electron microscopy imaging. PAN nanofibers are randomly distributed and fairly uniform nanofibers were obtained. Some negligible bead defect structure was observed at low magnification SEM images, as can be seen in Figure 4.9. More than 100 nanofibers were measured for diameters. Computed diameter distribution is presented in Figure 4.10. Minimum nanofiber diameter was 205nm and maximum nanofiber diameter was 544nm where mainly nanofiber diameters scattered between 320 and 440 nm and the average nanofiber diameter was calculated as 376nm.

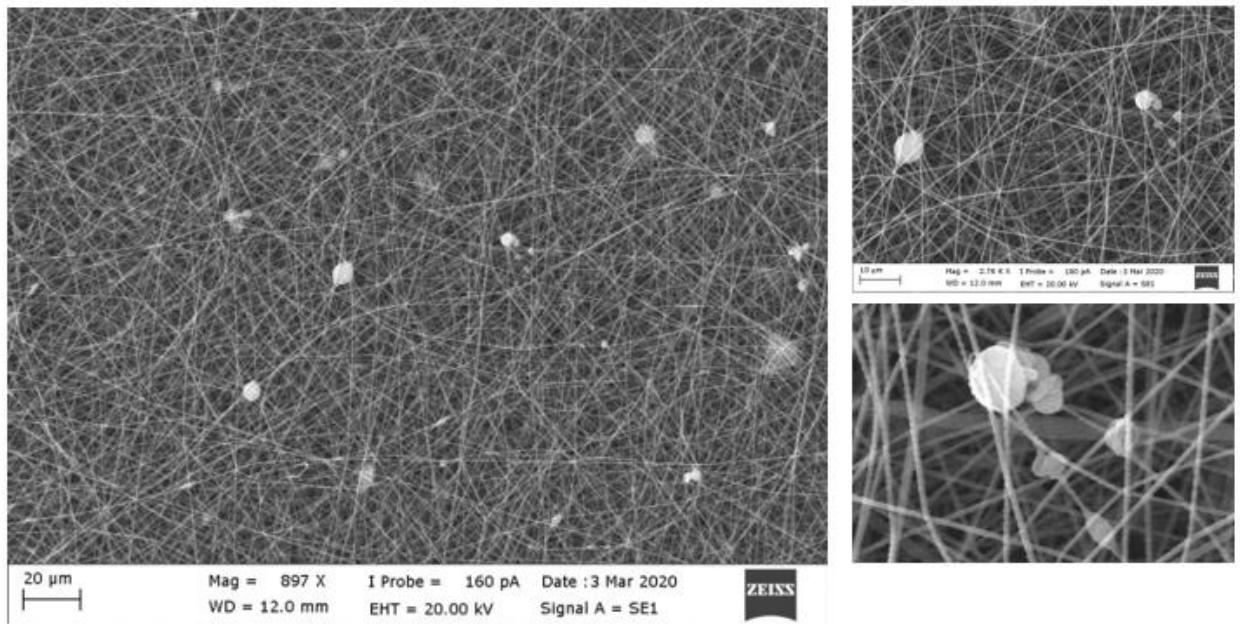

Figure 4.9. SEM Images of Electrospun PAN Nanofiber

Tightly interconnecting nanofibers are pretender for the thermal conduction path as thermal property enhancer of paraffin actuator in nanoscale. In Figure 4.11, the shown SEM image exhibits the interconnection hubs of the nanofibers where on a 12 micrometer square area 7 pieces' nanofiber cuts have 12 hubs. Computed total length of these cuts measured as 21.80 micronmeter. The volume of these nanofiber cuts is calculated with average nanofiber diameter of 376 nanometers as 2.419 cubic micrometers and as well as with density of 1.18g/cc, 2.85E-12g weight .

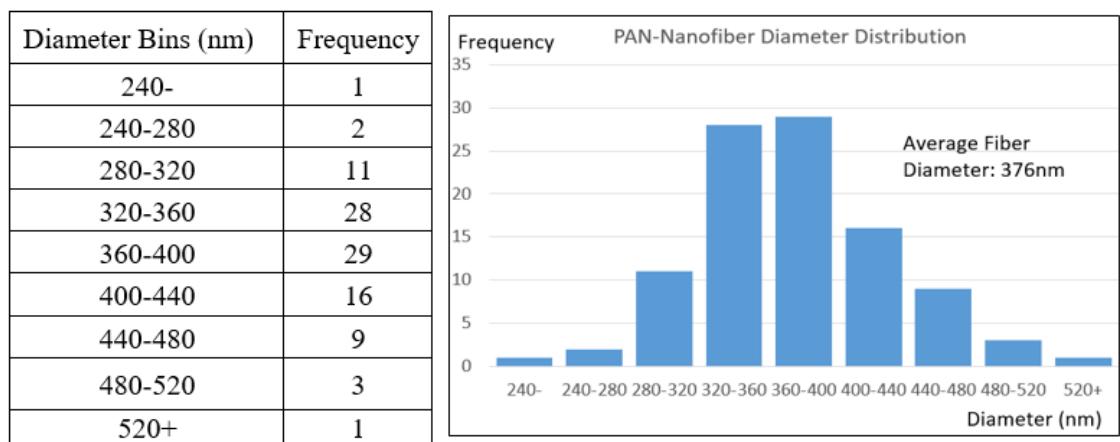

Figure 4.10. Diameter distribution of PAN Nanofibers

This tiny amount of 2.85E-12 g nanofiber revealed 12hubs, furthermore 0.45g PAN-Nanofiber which we have used for paraffin actuator sample P5, estimated, has 1.58E+11 interconnecting hubs. These extraordinary amount of hubs are expected to pass the thermal energy through nanocomposite structure and serves as a conductive network to enhance the thermal behavior of paraffin.

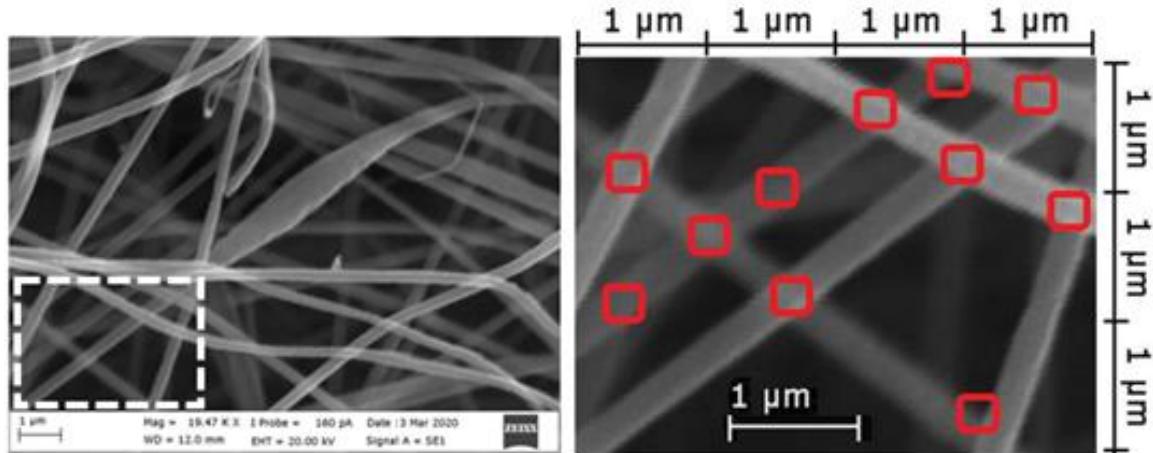

Figure 4.11. SEM Images of Electrospun PAN Nanofiber-interconnecting hubs

4.2.2. Paraffin-nanocomposite SEM and EDS results

In Figure 4.12-A, SEM images of Al_2O_3 -Paraffin nanocomposite show that the nanoparticles have spherical shape which are agglomerated and coated/encapsulated with paraffin (Figure 4.12-B). Right bottom side of Figure 4.12-C exhibits that there are still pure paraffin blocks which are not homogeneously mixed with nanoparticles. These pure paraffin block structures do not reflect the thermal conductive features of Al_2O_3 nanoparticles and diminish the overall thermal behavior enhancement. A better mixing method should be developed to minimize the pure paraffin blocks amount in the nanocomposite.

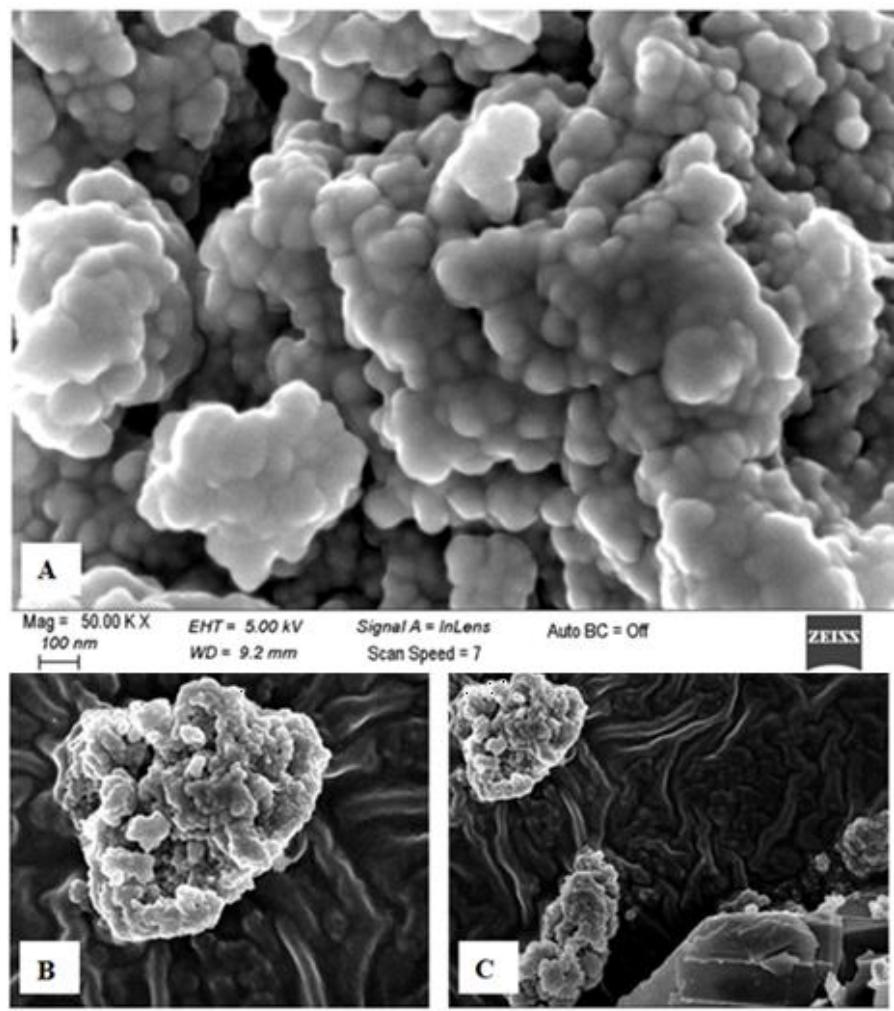

Figure 4.12. SEM images of Al_2O_3 -Nonadecane nanocomposite

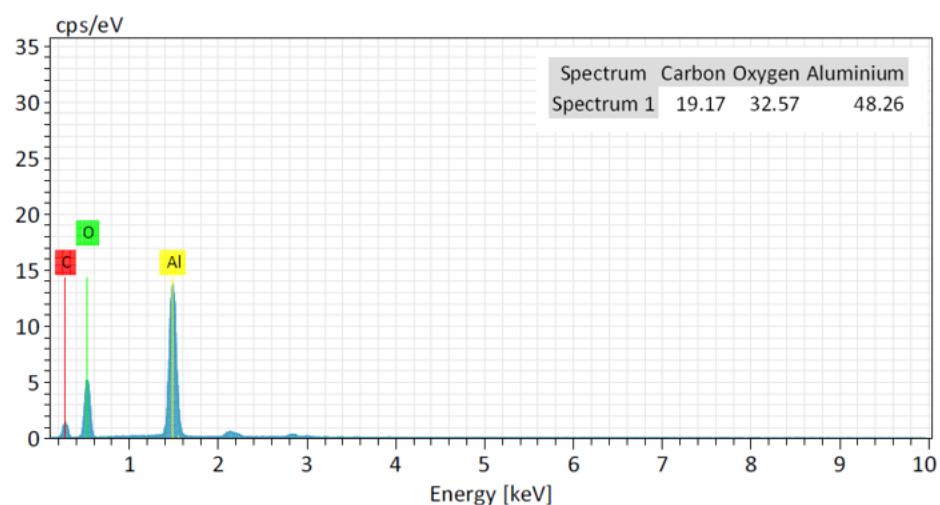

Figure 4.13. EDS image of Al_2O_3 -Nonadecane nanocomposite

Presence of aluminum atoms in the composition of sample at the atomic level is confirmed by EDS analysis. Figure 4.13 shows the peaks of atoms in accordance with presence in the nanostructure characterized via energy dispersive X-ray spectroscopy analysis.

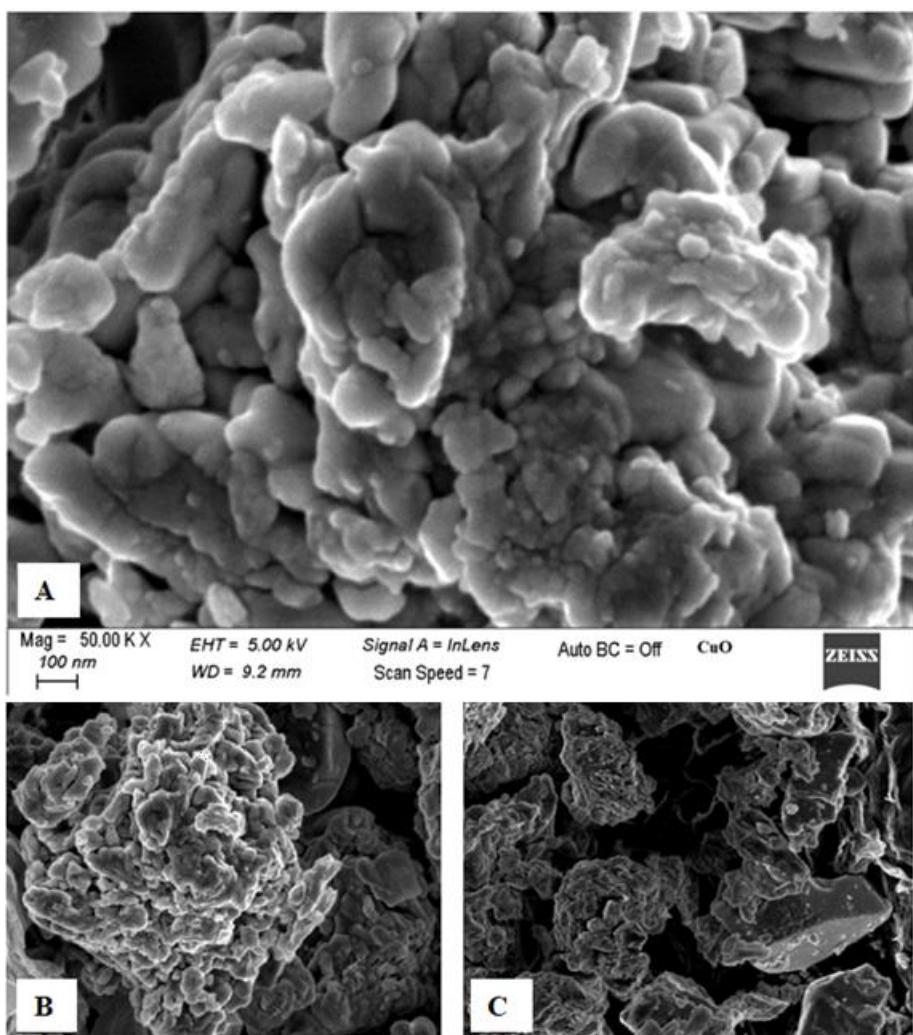

Figure 4.14. SEM images of CuO-Nonadecane nanocomposite

In Figure 4.14-A, SEM images of CuO-Paraffin nanocomposite show that the nanoparticles have non-spherical shape which are agglomerated and coated with paraffin (Figure 4.14-B). Right bottom side of Figure 4.14-C exhibits that there are still pure paraffin blocks, seen as Al_2O_3 -paraffin nanocomposite which are not homogeneously mixed with nanoparticles. These pure paraffin block structures do not reflect the thermal conductive features of CuO nanoparticles and diminish the overall

thermal behavior enhancement. A better mixing method should be developed to minimize the pure paraffin blocks amount in the nanocomposite.

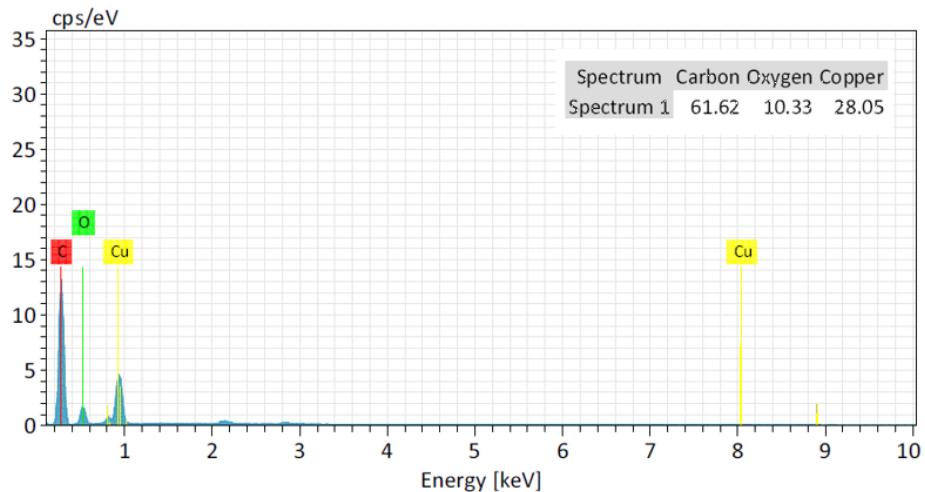

Figure 4.15. EDS image of CuO-Nonadecane nanocomposite

Presence of copper atoms in the composition of sample at the atomic level is confirmed by EDS analysis. Figure 4.15 shows the peaks of atoms in accordance with presence in the nanostructure characterized via energy dispersive X-ray spectroscopy analysis.

SEM images of Fe_3O_4 -paraffin nanocomposite in Figure 4.16-A show that the nanoparticles have semi-spherical shape which are agglomerated and coated with paraffin (Figure 4.16-B). Fe_3O_4 nanoparticles have smaller size in comparison with Al_2O_3 and CuO nanoparticles according to SEM images.

Presence of iron atoms in the composition of sample at the atomic level is confirmed by EDS analysis. Figure 4.17 shows the peaks of atoms in accordance with presence in the nanostructure characterized via energy dispersive X-ray spectroscopy analysis.

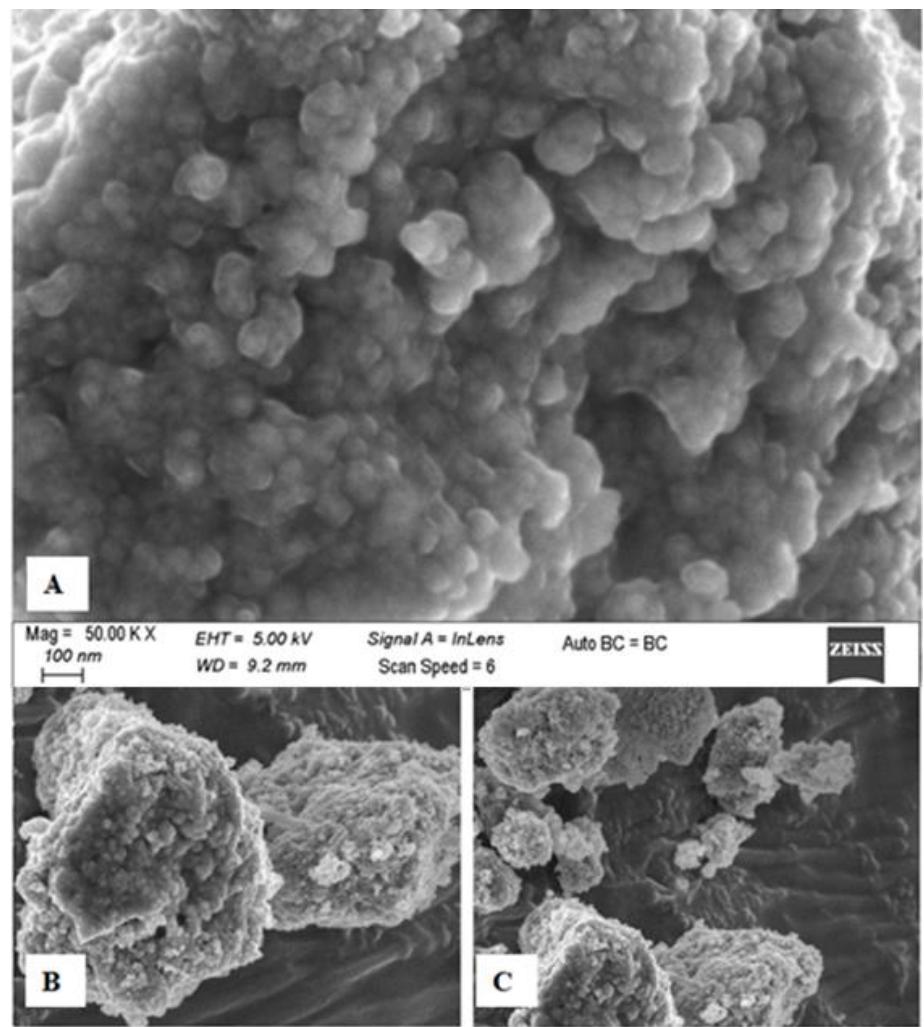

Figure 4.16. SEM images of Fe_3O_4 -Nonadecane nanocomposite

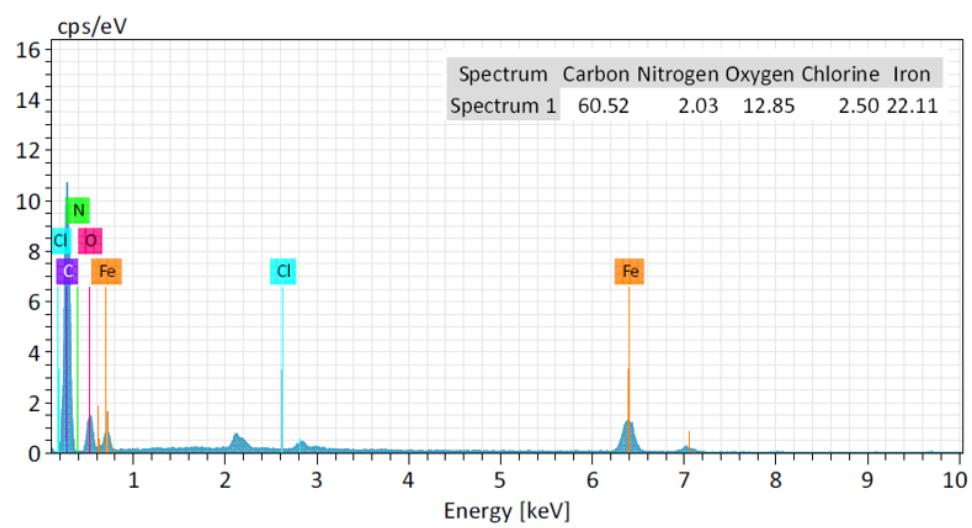

Figure 4.17. EDS image of Fe_3O_4 -Nonadecane nanocomposite

SEM images of ZnO-Paraffin nanocomposite in Figure 4.18-A show that the nanoparticles have hexagonal short-rod shape. The agglomeration is very limited incomparable with Al_2O_3 , CuO and Fe_3O_4 nanoparticle and coated with paraffin (Figure 4.18-B). Right bottom side of Figure 13-C exhibits that there are still pure paraffin blocks, seen as Al_2O_3 and CuO-paraffin nanocomposite which are not homogeneously mixed with nanoparticles. These pure paraffin block structures do not reflect the thermal conductive features of ZnO nanoparticles and diminish the overall thermal behavior enhancement. A better mixing method should be developed to minimize the pure paraffin blocks amount in the nanocomposite.

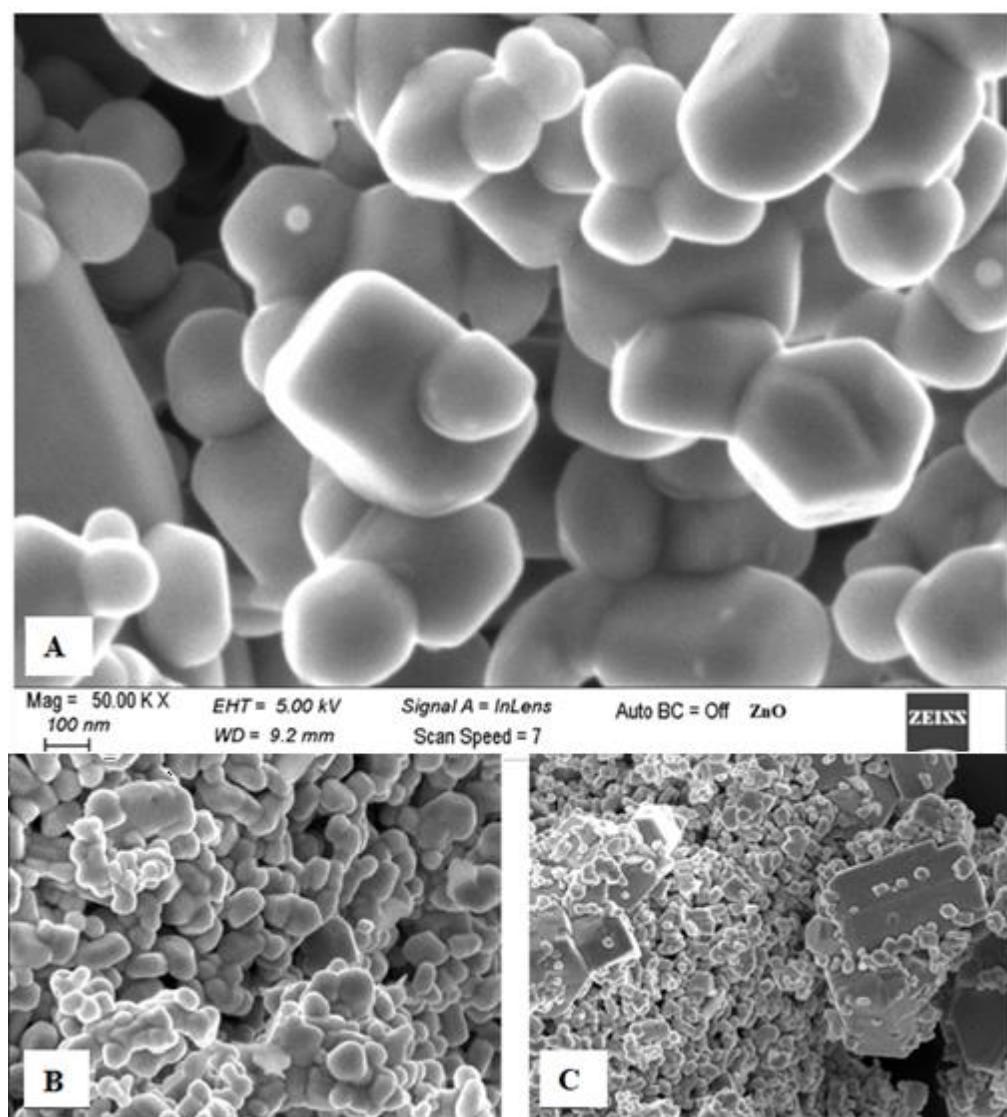

Figure 4.18. SEM images of ZnO-Nonadecane nanocomposite

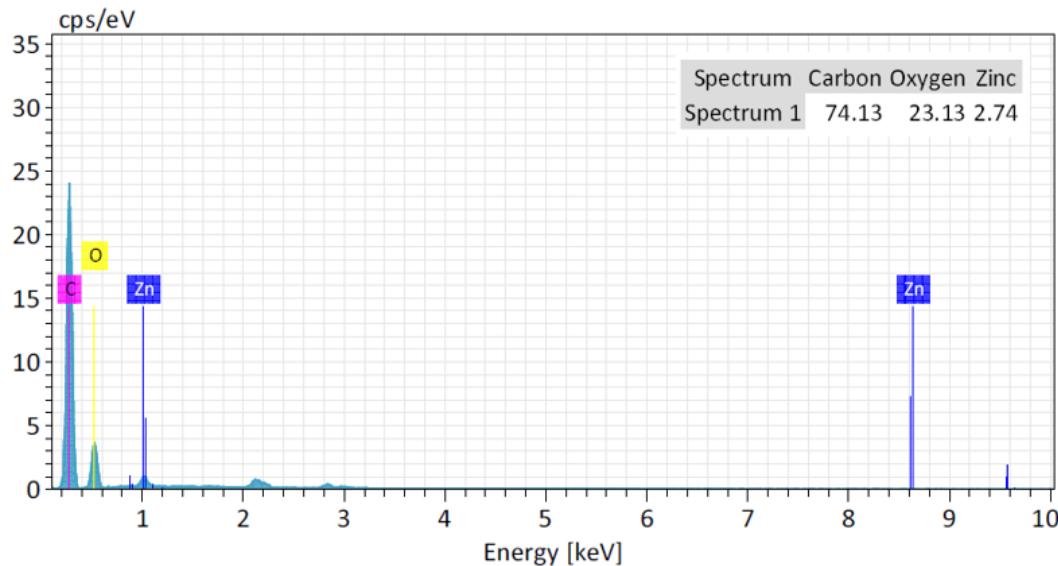

Figure 4.19. EDS image of ZnO-Nonadecane nanocomposite

Presence of zink atoms in the composition of sample at the atomic level is confirmed by EDS analysis. Figure 4.19 shows the peaks of atoms in accordance with precence in the nanostructure characterized via energy dispersive X-ray spectroscopy analysis.

SEM images of PAN Nanofiber-Paraffin nanocomposite in Figure 4.20-A show that the nanofibers are coated/encapsulated with paraffin (Figure 4.20-B). Interconnected network structure of pure PAN nanofibers is still existing after mixing with paraffin. Figure 4.20-C exhibits that the paraffin amount, which is not directly coating individual nanofibers, is encasing nanofiber bundles and forming fiber reinforced laminate-like structure. Thin paraffin laminate-like layers supported with nanofibers are meant to sense the temperature change more efficiently than the pure paraffin blocks found in metal oxide-paraffin nanocomposites. That could be the reason of better thermal hysteresis enhancement of PAN nanofiber-paraffin nanocomposite.

The EDS analyse results confirm that the PAN-nanofibers-paraffin nanocomposite has no external high conductive metalic content, and hysteresis enhancement is achieved just with PAN nanofibers. Figure 4.21 shows the peaks of atoms in accordance with precence in the nanostructure characterized via energy dispersive X-ray spectroscopy analysis.

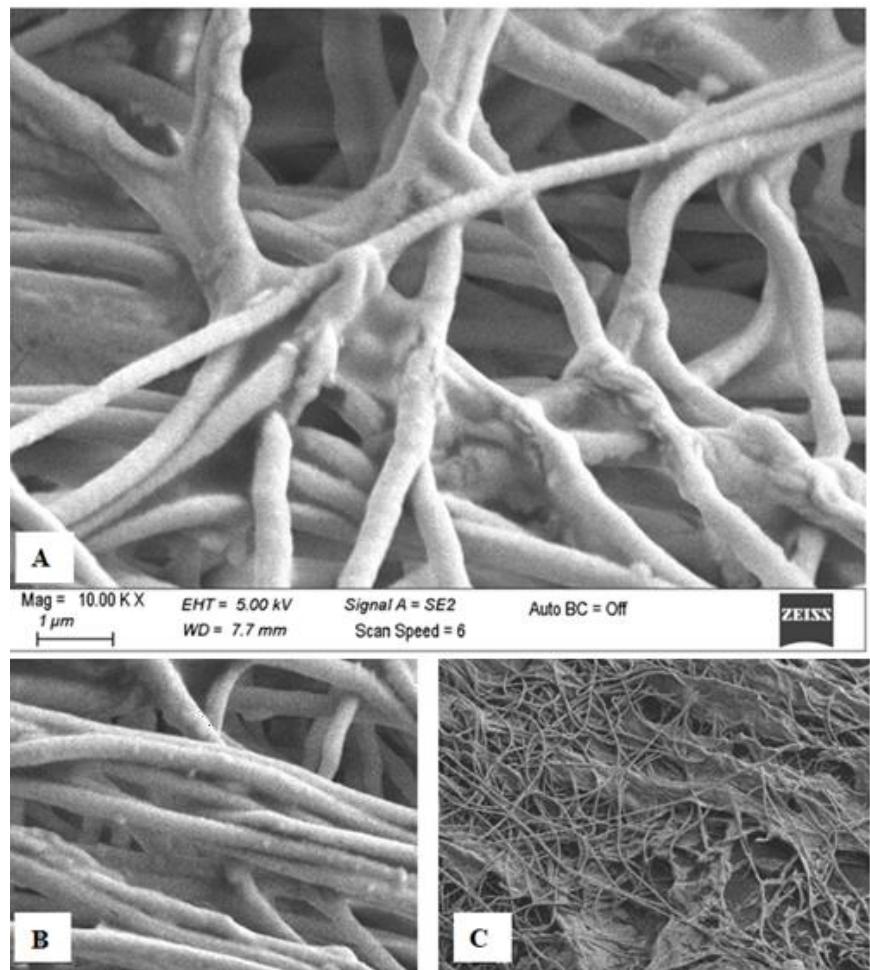

Figure 4.20. SEM images of PAN Nanofiber-Nonadecane nanocomposite

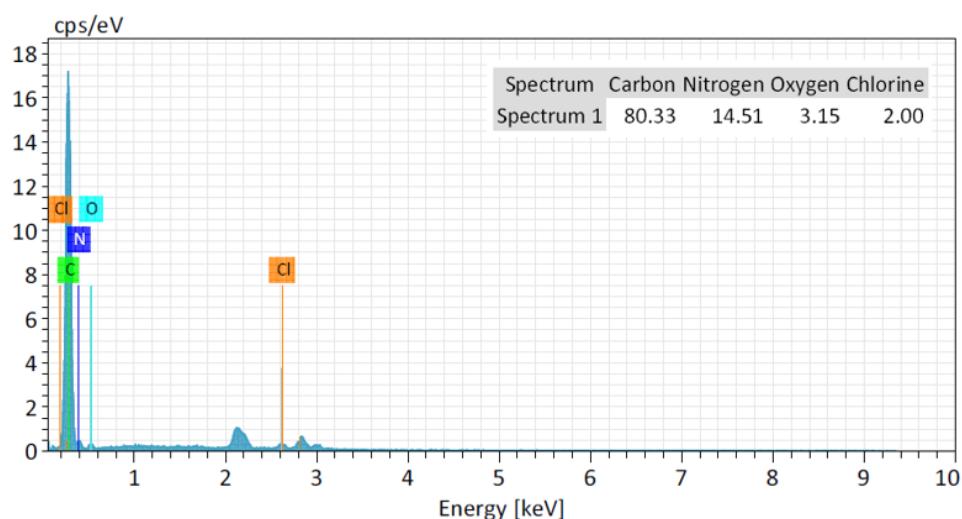

Figure 4.21. EDS image of PAN Nanofiber-Nonadecane nanocomposite

4.2.3. Thermal properties of pure nonadecane DSC and TGA results

DSC measurement showed in Figure 4.22 experimental melting and solidification curve obtained from pure nonadecane sample. The onset X temperature 31.01°C corresponds the start of phase transition. The peak temperature of 36.14°C corresponds the maximum energy absorption during melting. Solidification phase transition starts at onset X temperature of 30.07°C and maximum energy release occurs at peak temperature of 30.50°C during solidification.

Normalized enthalpy of melting is measured as 232.22 J/g and that of solidification 235.34 J/g. Enthalpy values are very close to results of Zhang's investigation. (Zhang et al, 2009). DSC analysis revealed that the solidification phase transition has a delay of 0.94°C with respect to melting phase transition and also solidification peak temperature has a delay of 5.64°C with respect to melting peak temperature. This delay of solidification with respect to melting points out the thermal hysteresis delay of paraffin actuator during heating and cooling thermal cycles.

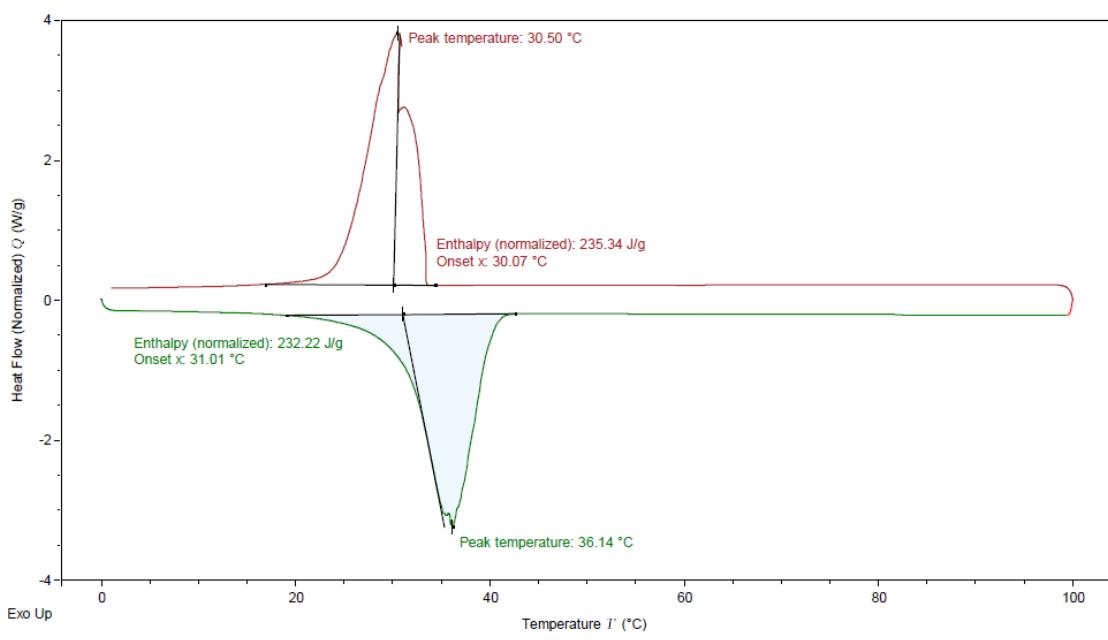

Figure 4.22. DSC curve of pure nonadecane

The TGA thermograms of pure nonadecane is shown in Figure 4.23. Pure n-nonadecane begins to degrade at approximately 145°C and it completely loses its weight at 275°C. The TGA thermogram of nonadecane exhibits a one step and sharp process without any remaining residuals. This reveals the purity of the nonadecane sample composed of a short linear alkane molecules C₁₉H₄₀.The sharp weight loss of nonadecane without residual is in agreement with the investigation of Timurah et.al. (K. Timuah et al, 2015)

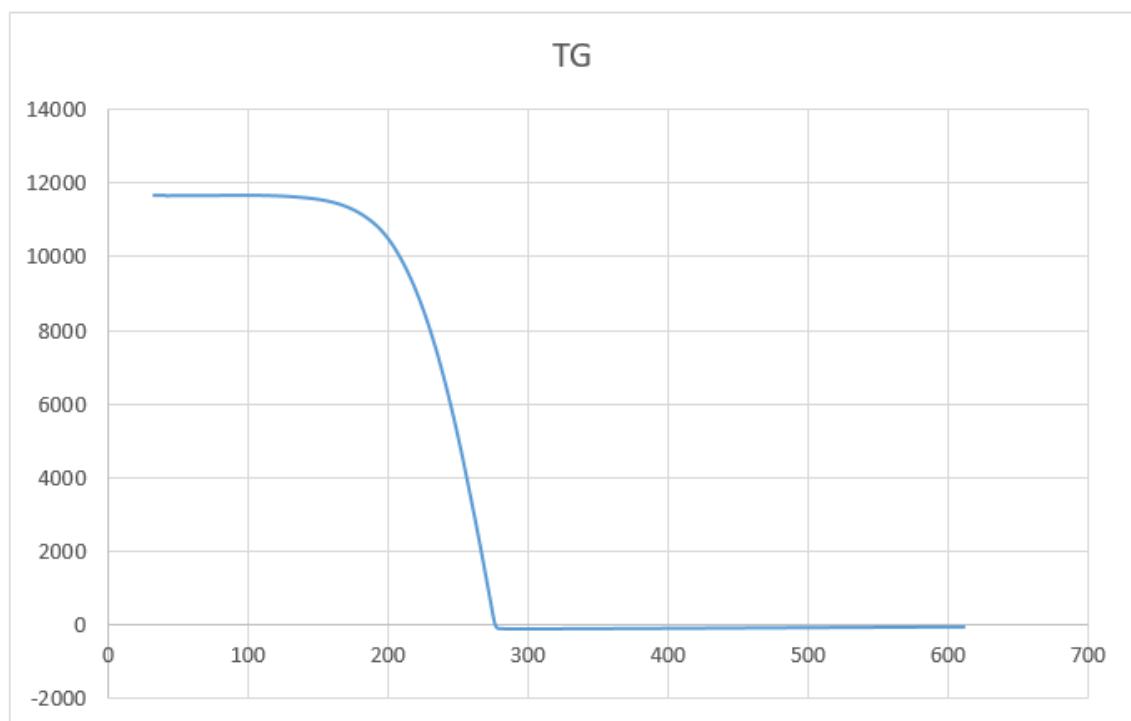

Figure 4.23. TGA curve of pure nonadecane

4.2.4. Dispersion thermal stability test results

High temperature dispersion thermal stability test is performed to determine the precipitation behavior of paraffin-nanocomposites at 100°C which is about 70°C higher than melting point of nonadecane. Figure 4.24 shows the photo-images and the CT - images at the same time laps. While CT-images are presenting the inner density homogeneity, photo-images are presenting the transparency/saturation of the nanocomposites from outside.

Samples of high temperature test, are seen at Figure 4.24-A2 CT-images, exhibiting light dots assigning very low density caused by air gaps and dark dots assigning very dense structure caused by agglomeration of nanoparticles, especially H1 and H3 including dark dots and H4 and H5 white dots. Sample H2 has light and dark dots dispersed relatively small sized and more homogenous.

Figure19-B1 shows that nonadecane at 100°C in 5 minutes changes its phase from solid to liquid, where the sample H6 transforms to transparent status. Although paraffin is in liquid phase, an obvious precipitation is seen only at sample H2. Samples H1 and H3 indicates a particular precipitation at bottom of the container. Figure 4.24-B2 exhibits that the light and dark dots at samples H1, H2 and H3 disappear from start of the test to 5th minute. This denotes that the precipitation of the nanoparticles sweeps down the non-uniformities like agglomerated structures and air gaps. Samples H4, H5, H6 demonstrate no trace of precipitation at the bottom of the container. On the other hand, in these three samples, light dots indicating air gaps conjoined together and become larger and more visible. This reveals that the air gaps do not diffuse in paraffin during expansion and phase change of paraffin from solid to liquid. Instead, it pushes the air gaps to each other and generates larger bubbles. Storage from 5th minute to 10th minute dark area, indicating precipitation at samples H1, H2 and H3, becomes longer. From 10th to 20th minute, a clear transparency comes in view where the floating nanoparticles sunk down, as seen in Figure19-C1 to D1 and E1. At sample H2, this transparency improvement can be seen apparently. As a proof of it, Figure 4.24 C2 to D2 and E2 the bottom of container becomes more and more dense with the compacting of precipitated nanoparticles on each other. In the meantime, again at samples H4, H5 and H6 no trace of precipitation is revealed, neither at CT-Imaging, nor at Photo-Imaging.

According to high temperature dispersion thermal stability test result, it is concluded to perform the second level hysteresis test after a 20 minutes' storage of paraffin actuators at 100°C.

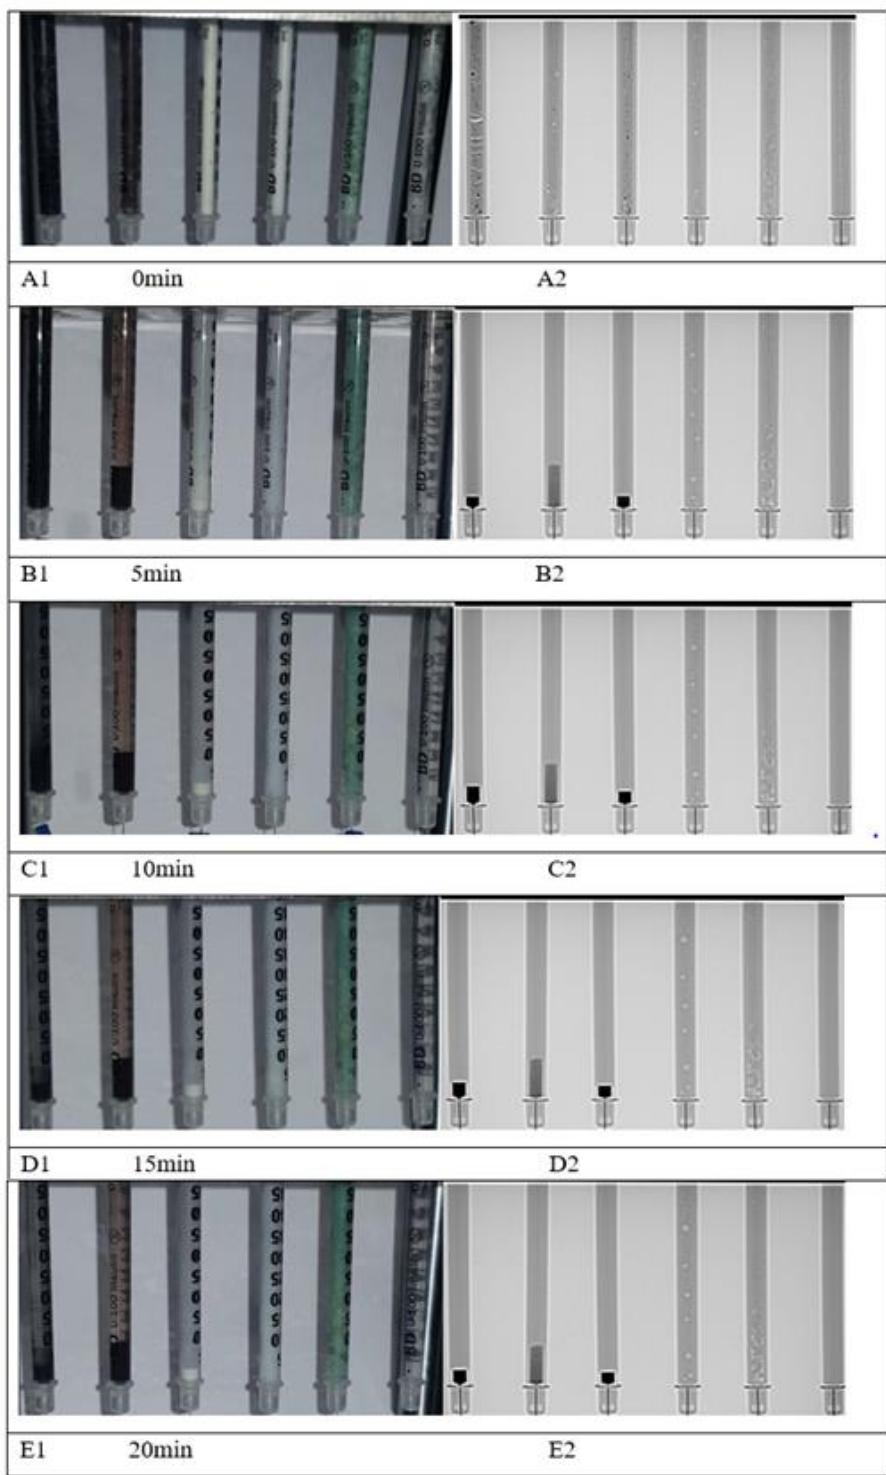

Figure 4.24. Dispersion Thermal Stability Test at 100°C, photo-images and CT-images, A1 and A2 at test begin, B1 and B2 at 5th min, C1 and C2 at 10th min, D1 and D2 15th min, E1 and E2 at 20th min

Results of low temperature thermal stability tests are shown in Figure 4.25. This test at 45°C provides an observation for smooth precipitation of nanoparticles. Top temperature of this test coincides with the top temperature of thermal hysteresis measurement which can supply an idea about the dispersion morphology of nanocomposite in paraffin actuator subjected to thermal hysteresis measurement during phase change.

Figure 4.25-A2 to D2 exhibits no precipitation at the first 6 minutes of storage in the nanocomposite structure which means the paraffin is still in solid phase. After 8th minute a very small amount of precipitation is seen at the bottom of the sample L3. Figure 4.25-E2 shows the precipitation of the nanoparticles at samples L1, L2 and L3 which means the nanocomposites start phase change from solid to liquid. Precipitation amount is increasing gradually from 10th minute to 20th minute at samples L1, L2 and L3 produced with CuO, Fe₃O₄ and ZnO nanoparticles.

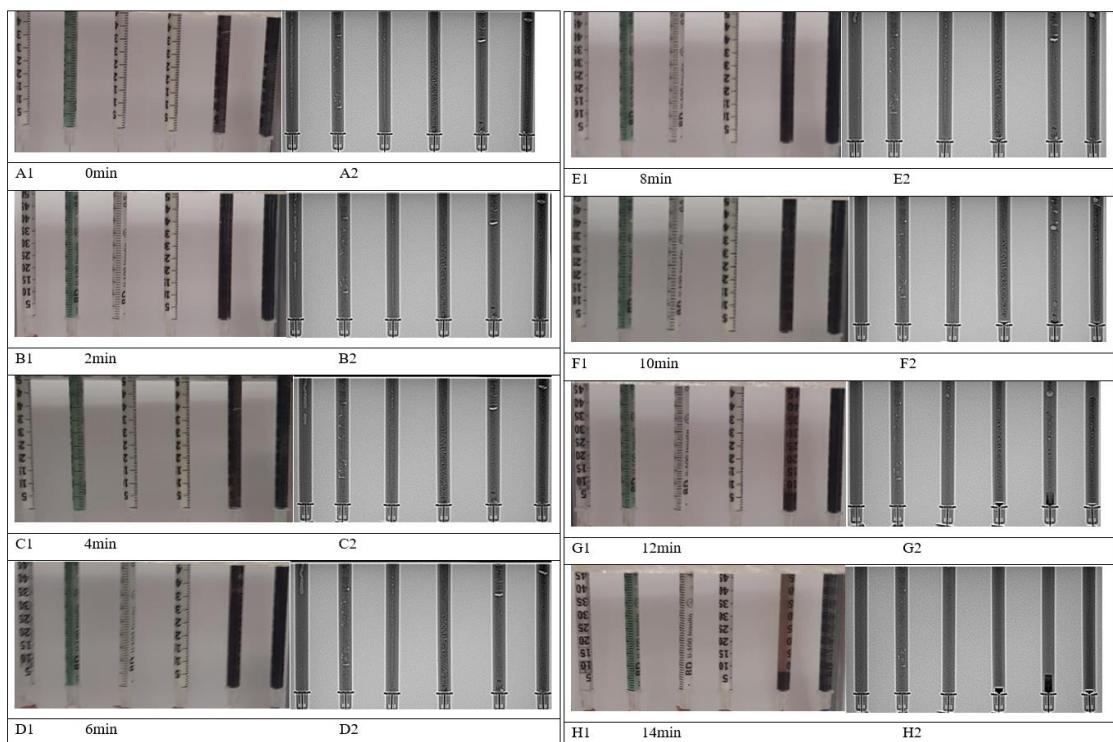

Figure 4.25. Dispersion Thermal Stability Test at 45°C, photo-images and CT-images , A1 and A2 at test begin,B1 and B2 at 2nd min, C1 and C2 at 4th min, D1 and D2 at 6th min, E1 and E2 at 8th min, F1 and F2 at 10th min, G1 and G2 at 12th min, H1 and H2 at 14th min, I1 and I2 at 16th min, J1 and J2 at 18th min, K1 and K2 at 20th min

4.2.5. Thermal hysteresis test results

The higher thermal hysteresis value means a longer time spent for valve closing of thermostat due to time delay of paraffin actuator. For this reason, lower thermal hysteresis value is expected from paraffin actuator providing higher control performance for thermal management systems.

First level hysteresis test was performed with paraffin actuators where no precipitation in the paraffin nanocomposites occurred. High temperature dispersion thermal stability test revealed that at 100°C 20-minute storage is enough for the almost precipitation of the metal oxide–paraffin nanocomposites. Therefore, the second level hysteresis test was performed after 20-minute storage of paraffin actuator in an oven at 100°C.

Hysteresis curves of paraffin actuators are shown in Figure 4.26 to Figure 4.31, measured before the storage at 100°C and labeled as hysteresis curve-pre and measured after storage at 100°C and labeled as curve-post. An overlapped hysteresis curve between 2 to 4mm lift is particularly depicted to analyse the hysteresis diminution.

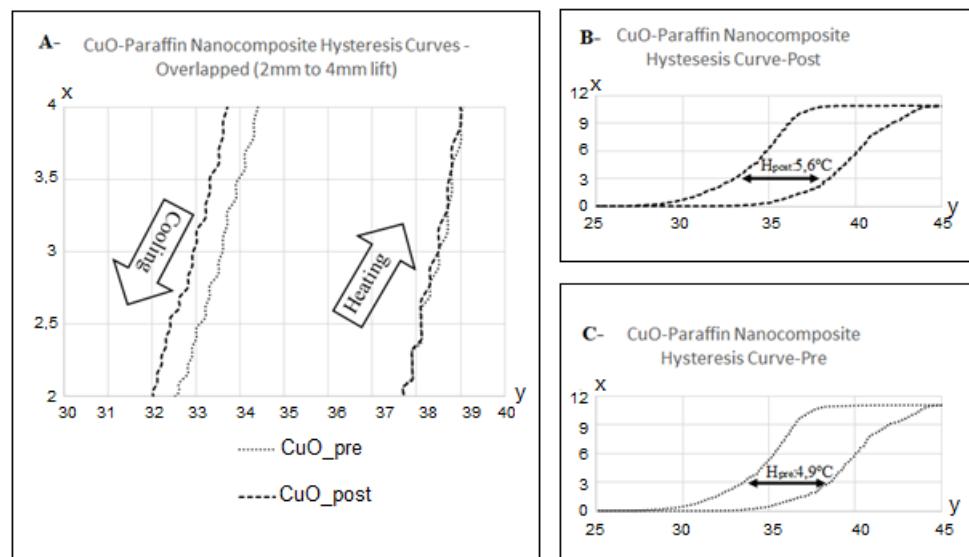

Figure 4.26. TH of P1 with CuO-Paraffin Nanocomposite, A-2mm to 4mm lift overlapped curves, B-Hysteresis after 100°C Storage C-Hysteresis before 100°C Storage

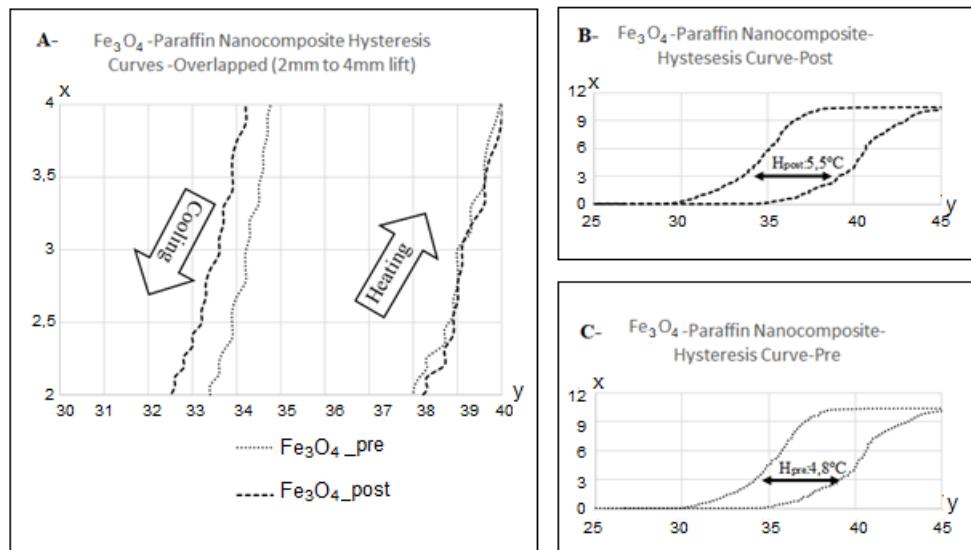

Figure 4.27. TH of P2 with Fe_3O_4 -paraffin nanocomposite, A-2mm to 4mm lift overlapped curves, B-Hysteresis after 100°C Storage C-Hysteresis before 100°C Storage

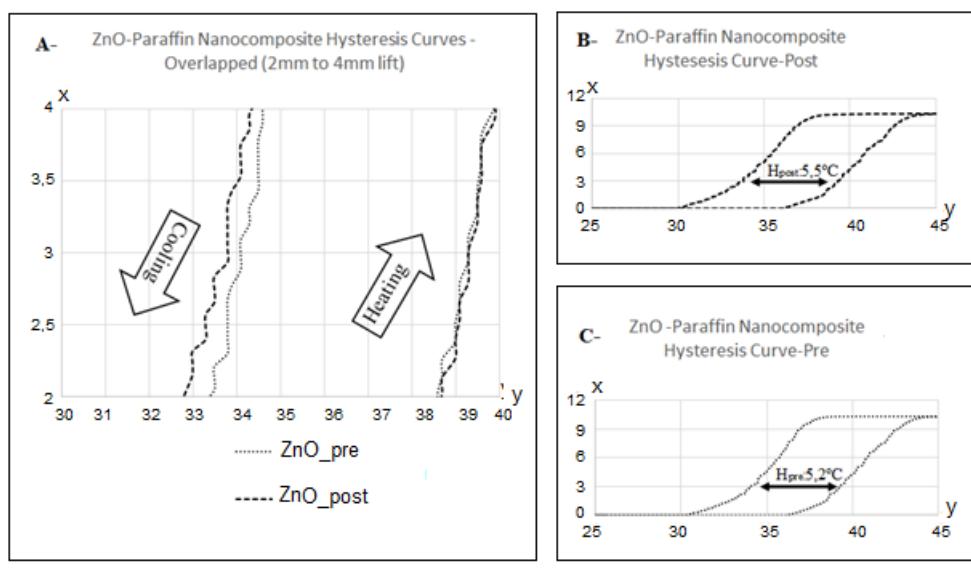

Figure 4.28. TH of P3 with ZnO-Paraffin Nanocomposite, A-2mm to 4mm lift overlapped curves, B-Hysteresis after 100°C Storage C-Hysteresis before 100°C Storage

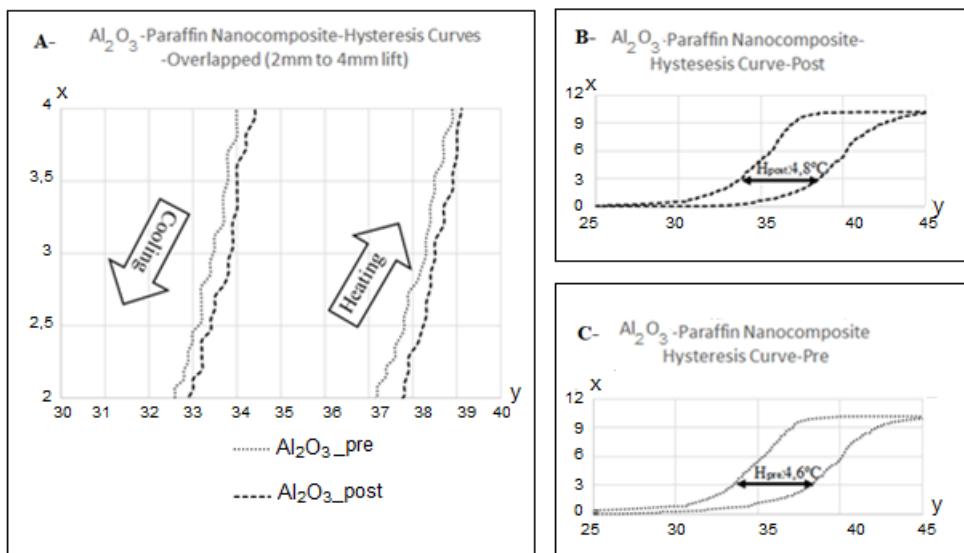

Figure 4.29. TH of P4 with Al_2O_3 -paraffin nanocomposite, A-2mm to 4mm lift overlapped curves, B-Hysteresis after 100°C Storage C-Hysteresis before 100°C Storage

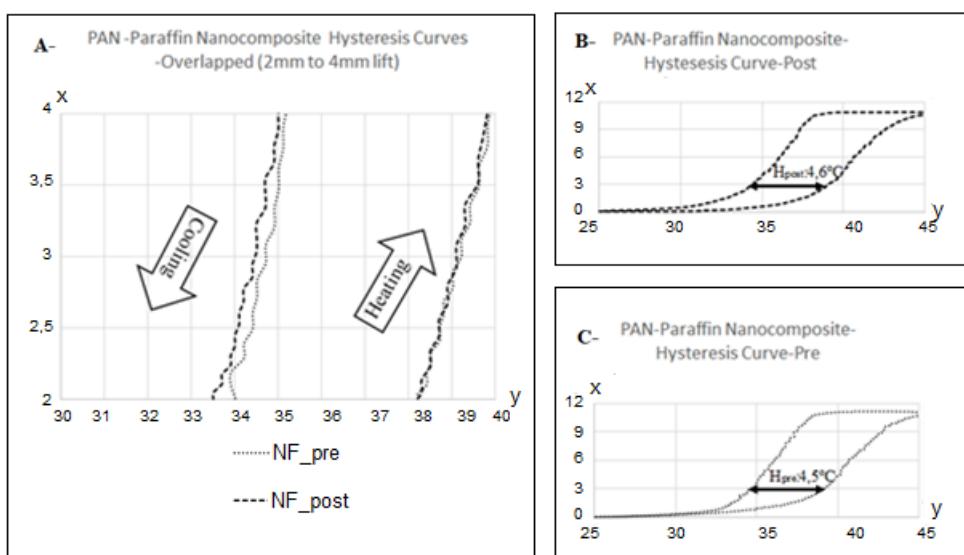

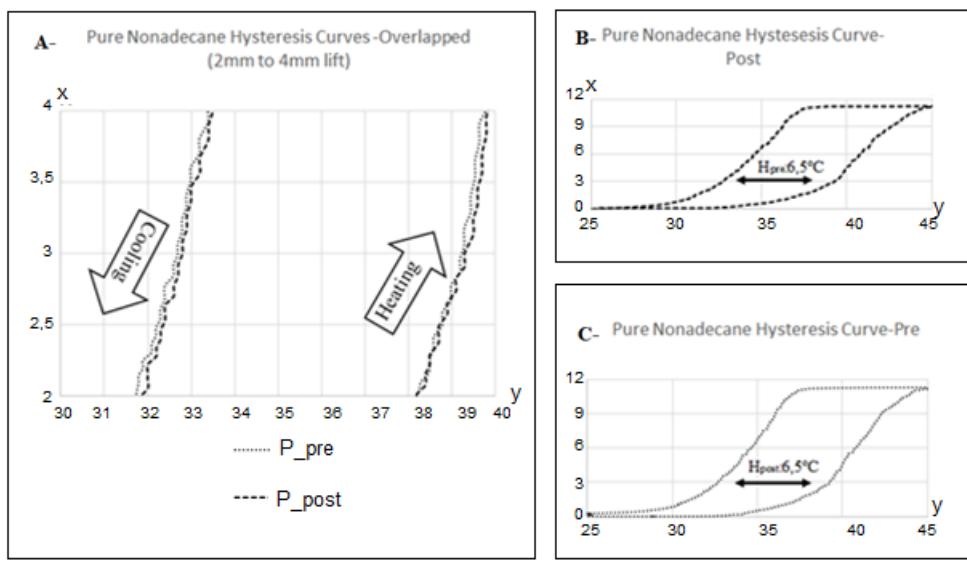

Figure 4.30. TH of P5 with PAN nanofiber-paraffin nanocomposite, A-2mm to 4mm lift overlapped curves, B-Hysteresis after 100°C Storage C-Hysteresis before 100°C Storage

x axis indicates the temperature in °C , y axis indicates the opening lift of paraffin actuator in mm

Figure 4.31. TH of P6 Paraffin Actuator with Pure Paraffin, A-2mm to 4mm lift overlapped curves, B-Hysteresis after 100°C Storage C-Hysteresis before 100°C Storage.

Figure 4.26A , Figure 4.27A and Figure 4.28A depict the overlapped hysteresis curves of first level and second level measurements for samples P1, P2 and P3. Curves are in agreement for both measurement levels at heating period where a hysteresis diminution occurs at cooling period. Figure 4.29A depicts a shifted curve at heating and cooling period where a limited hysteresis diminution is registered. Figure 4.30A reveals a very limited hysteresis diminution at cooling period where at heating period the curves of first and second level measurement are very close to each other. Figure 4.31A indicates no noteworthy change at hysteresis curves from first level to second level hysteresis measurement as expected sample P6 produced with pure paraffin.

Sample P5 revealed barely hysteresis diminution 2.2% as expected where the nanofiber density is close to paraffin density. Interconnected PAN nanofiber structure stands in the liquid paraffin like a nano scaled skeleton. This very low change at thermal hysteresis complies with dispersion thermal stability results of H5 and L5 samples.

Sample P4 has shown less hysteresis diminution than the other metal oxide samples, from first level to second level hysteresis measurements, which coincides with results of

high and low temperature dispersion thermal stability test of samples H4 and L4 where no precipitation was detected. This can be effect of the high surface area of Al_2O_3 nanoparticles with $140 \text{ m}^2/\text{g}$ higher specific surface area and lower density in comparison with other investigated metal oxide nanoparticle additives.

Table 4.2. Results of first level hysteresis measurement before 100°C storage and second level hysteresis measurement after 100°C storage.

Sample Name	Sample Status	Temperatur e of 3mm lift while 1°C/min heating up	Temperatur e of 3mm lift while 1°C/min cooling down	Thermal Hysteresis at 3mm Lift	Change at Thermal Hysteresis
P1	First level TH, Pre 100°C storage	38.50°C	33.60°C	4.90°C	0.7 °C
	Second level TH, Post 100°C storage	38.50°C	32.90°C	5.60°C	
P2	First level TH, Pre 100°C storage	39.00°C	34.20°C	4.80°C	0.7 °C
	Second level TH, Post 100°C storage	39.10°C	33.60°C	5.50°C	
P3	First level TH, Pre 100°C storage	39.30°C	34.10°C	5.20°C	0.3 °C
	Second level TH, Post 100°C storage	39.30°C	33.80°C	5.50°C	
P4	First level TH, Pre 100°C storage	38.50°C	33.90°C	4.60°C	0.2 °C
	Second level TH, Post 100°C storage	38.30°C	33.50°C	4.80°C	
P5	First level TH, Pre 100°C storage	39.20°C	34.70°C	4.50°C	0.1 °C
	Second level TH, Post 100°C storage	39.10°C	34.50°C	4.60°C	
P6	First level TH, Pre 100°C storage	39.20°C	32.70°C	6.50°C	0.0 °C
	Second level TH, Post 100°C storage	39.30°C	32.80°C	6.50°C	

Table 4.2 demonstrates the hysteresis enhancement of paraffin actuators using paraffin-nanocomposite structure. All the samples P1, P2, P3, P4 and P5 produced with nanostructure addition has a significant hysteresis improvement at first level measurement in comparison with P6 produced with pure paraffin, with following values

24.6, 26.2, 20.0, 29.2, 30.8 % respectively. Nevertheless, after high temperature storage, samples P1, P2 and P3 lose their enhancement substantially via precipitation of nanoparticles and come down an enhancement of 13.8, 15.4 and 15.4% respectively, in comparison with sample P6. Samples P4 and P5 maintain their hysteresis essentially of 26.2 and 29.2% respectively, in comparison with sample P6.

5. CONCLUSION

5.1. Effect of the Number of Carbon in Paraffin on Interaction Nanofibers

The interaction of liquid paraffin with PVA nanofiber surfaces was investigated by using electrospun PVA nanofibrous mat and liquid paraffins with different amount of carbon in their structures. Microscopic images revealed that liquid paraffin could be held on the surface on the PVA nanofibers. Contact angle measurement results revealed that heptadecane has the highest and pentadecane has the lowest contact angle on PVA nanofibrous mat structures. As a conclusion, wettability of the PVA nanofibers by liquid paraffin can be enhanced if the paraffin is used which has less number of carbon atoms.

5.2. Paraffin/PAN Hybrid Nanofibers for Thermal Hysteresis Enhancement

Paraffins with different melting temperatures were successfully loaded to PAN nanofiber via electrospinning process at the ambient temperature. A simple preparation procedure was followed by mixing paraffin in PAN/DMF solution at over melting temperature of paraffin via magnetic stirring. After paraffin was melted in the solution, the mixture was slowly cooled down to the ambient temperature with continuous stirring. Homogeneous colloidal molten paraffin particles transformed to homogenous suspension just by cooling the system down under melting temperature according to paraffin type. Paraffins with melting temperatures of 32, 58, 89 and 114°C were included in PAN nanofibers.

The addition of paraffin reduced the PAN nanofiber diameter from 376nm (neat PAN) to as low as 214nm under the same electrospinning parameters. Enthalpies of the paraffin portion in P/PAN nanofibers increased from 9.6 to 101.5 J/g respectively by increasing melting point of the loaded paraffin. FTIR results demonstrating the positions of the corresponding peaks of PAN molecules in P/PAN nanofibers didn't change significantly compared to neat PAN nanofibers. These revealed that since there was not a chemical interaction between PAN and paraffin molecules both at solution

and nanofiber preparation processes, the phase transition property of paraffin could be very applicable for the cyclic usage of P/PAN nanofibers in thermal regulation applications. P/PAN hybrid nanofibers were successfully applied in paraffin actuator which is adequate for e-vehicle battery cooling systems.

Paraffin compound of the paraffin actuator was prepared with a mixture of pure paraffin and P/PAN nanofiber with weight ratios of 2.5, 5, 7.5 and 10%. Hysteresis value at 3mm stroke was improved at 1.7, 3.4, 11.9 and 15.3% levels respectively. The effect of thermal percolation was observed between the samples with 5.0 and 7.5% nanofiber additions. Effect of thermal conductivity contrast on the nanocomposite structure was observed between solid and liquid paraffins by the thermal response performance of the paraffin actuator, which showed difference during heating and cooling periods due to weight ratio of hybrid nanofibers in paraffin compound.

5.3. Thermal Hysteresis Enhancement and Dispersion Thermal Stability

A uniform PAN-Nanofiber structure was produced via electrospinning. Nonadecane paraffin with melting point of 32 °C is thermally characterized as a phase change material. Nanocomposite materials prepared via addition of CuO, Fe₃O₄, ZnO, Al₂O₃ nanoparticles and PAN nanofibers into nonadecane wt. % of 10 for the thermal behavior enhancement. Metal oxide- and nanofiber-paraffin nanocomposites are characterized by SEM and EDS analysis.

Besides pure paraffin compound, the produced nanocomposites are used as thermal expansion material in paraffin actuator. CuO, Fe₃O₄, ZnO, Al₂O₃ nanoparticles and nanofiber addition have successfully improved the thermal hysteresis value by 24.6, 26.2, 20.0, 29.2 and 30.8% for the samples respectively compared with pure paraffin at first level hysteresis test.

Although PAN-nanofiber has considerably lower thermal conductivity compared with investigated metal oxide nanoparticles, it revealed better thermal hysteresis enhancement in terms of paraffin actuator application due to the thermal conductive

network in nanocomposites. This thermal conductive structure built-up by interconnected fiber network is demonstrated with SEM images. Nanofiber reinforced paraffin actuator exhibited 30.8% before precipitation and 29.2% after precipitation. First and second level hysteresis test has proved that PAN-nanofiber based paraffin nanocomposite achieved best thermal behavior enhancement in terms of thermal hysteresis.

Effect of thermal dispersion stability on hysteresis performance of the nanocomposites is also investigated to ensure the long term consistent hysteresis performances advantages in paraffin actuator. PAN nanofiber added paraffin compound revealed a minor precipitation effect on hysteresis performance with a loss of 2.2%.

Thermal dispersion stability of the nanocomposites is comprehended via computer tomographic (CT) investigation in two different temperatures. The excessive precipitation of CuO-, Fe₃O₄- and ZnO-paraffin nanocomposite observed within 5 minutes at 100 °C where a gradually precipitation within 20 minutes at 45 °C is exposed. Precipitation of PAN nanofiber and Al₂O₃-paraffin nanocomposite was not visually detectable via CT-image and photo-image throughputs. Effect of thermal dispersion stability on hysteresis performance of the nanocomposites is also investigated to ensure the long term consistent hysteresis performance advantages in paraffin actuator. PAN nanofiber added paraffin compound revealed a minor precipitation effect on hysteresis performance.

Second level hysteresis test results were compliant with dispersion thermal stability test results where the highest hysteresis diminution occurred at samples of CuO-paraffin, Fe₃O₄-paraffin and ZnO-paraffin nanocomposites which are subjected to strong precipitation. Second level hysteresis test is performed after heat storage of paraffin actuators at 100°C and following hysteresis diminution is revealed as 14.3, 14.6, 5.8, 4.3, 2.2 % respectively.

RESUME

Name Surname : AHMET KUTLU

Place and Date of Birth : 17.12.1979

Foreign Languages : GERMAN, ENGLISH

Education Status

High School : S.SCIENCE HIGH SCHOOL, ANKARA

Bachelor's : ULUDAG UNIVERSITY, BURSA

Master's : UNIVERSITY OF REUTLINGEN, GERMANY

Work Experience :

-RESEARCH AND DEVELOPMENT ENGINEER FOR CONSTRUCTION AND STRESS ANALYSIS IN AIRBUS A380,A350,A400M AIRCRAFTS PROGRAMMS

-RESEARCH AND DEVELOPMENT PROJECT SUPERVISOR FOR THERMAL MANAGEMENT SYSTEMS OF (VW) EA211, EA288 CAR ENGINE PROGRAMMS AND (RENAULT) K9K, HR10, HR12 CAR ENGINE PROGRAMMS AT TIER1 DEVELOPMENT AND PRODUCT SUPPLIER.

Contact (e-mail) : benkutlu@yahoo.com

Publications :

-Kutlu, A., Eren, R., Aykut, Y., (2021). Paraffin/polyacrylonitrile hybrid nanofibers for thermal hysteresis enhancement of paraffin actuators,*Journal of Industrial Textiles*, January 24 2021

-Kutlu, A., Eren, R., Aykut, Y., (2019). Effect of the Number of Carbon in Paraffin on Interaction with PVA Nanofiber Mat, *17th National 3rd International the Recent Progress Symposium on Textile Technology and Chemistry*, 20-22,November 2019
